Curatorial Reports

The Curatorial Reports of the Nova Scotia Museum make technical information on museum collections, programs, procedures and research accessible to interested readers.

This report contains the preliminary results of an on-going research program of the Museum. It may be cited in publications, but its manuscript status should be clearly noted.

Executive Summary

Archival institutions such as Museums of Natural History are repositories for important records of elements of natural history landscapes over a geographic range and over time.

The Mollusca collection of the Nova Scotia Museum is one example of where early (19th century) provincial collections have been documented and supplemented by further work over the following 143 years. Contemporary field investigations by the Nova Scotia Museum and agencies such as the Nova Scotia Department of Natural Resources have allowed for a systematic documentation of the distribution of a selected group, the freshwater mussels, in large portions of the province.

Although this group comprises only 10 extant and one regionally-extirpated species, these collections represent important species which have been recognized as sensitive indicators of environmental modification as well as larger scale climatic change.

A consolidation of these data (1083 specimen lots), including 164 collections from other North American and European sites allows a clear definition of baseline distributions, primarily in the 20th and beginning of the 21st century. The report summarizes collection data in the form of species accounts, supplemented by distribution maps, as well as specific biological information (in a Nova Scotia context) including the requirement for a fish host during early development; a further limitation on their ability to expand ranges.

A selected suite of data fields for each documented collection of freshwater mussels in the Collection of the Nova Scotia Museum is appended.

Recommendations are made for future work.

Acknowledgements

The author would like to acknowledge the Nova Scotia Museum for providing access to what is now a comprehensive collection of the freshwater mussels of Nova Scotia. The collection has resulted from many years of field work and documentation by members of staff, volunteers, students, professional partners and the general public. In particular the efforts of Leslie Pezzack, who managed the data, photography and imagery, and Andrew Hebda, of the Nova Scotia Museum, for his support and encouragement in the production of this manuscript. Donnie Anderson, Doug Archibald, Dan Banks, Jenny Costelo, Mark Elderkin, Ross Hall, Mark Pulsifer and Terry Power of Nova Scotia Department of Natural Resources should be recognised for their work in the recent survey which produced so much valuable new information. The contributions of all are recognised in the database shown in Appendices II and III. The author also wishes to thank Etta Moffatt for graphic design and layout of this manuscript. Critical reviews of the manuscript by Joe Carney, Rick Harbo and Janice Smith are greatly appreciated.

Introduction

Museums of Natural History are custodians of collections of specimens of animals, plants, rocks, minerals and fossils that constitute our natural heritage. Most nations have such museums, usually located in the national capitals, but provinces, states, towns and smaller communities as well as private institutions and individuals also recognize the importance of such natural history collections. In Europe, beginning in the 17th century, collections were maintained privately and kept in order as "cabinets of curiosity". With the recognition of the research and educational values of collections and the escalation of exploration and scientific enquiry into the natural world, new scales of management were developed. The adoption of systematics, especially that initiated by Carl Linnaeus (1758), stimulated the collection and description of species, the exchange and publication of new species, and concurrently, the growth of museum collections. As such collections grew in size and number, the physical order of specimens was augmented by accession records, card catalogues and subsequently computer-based catalogues. Over more than 400 years museums have become institutions that are valued by their communities as a source of knowledge and inspiration in science, literature, design, education and enterprise.

The Nova Scotia Museum (NSM) originated as the Nova Scotia Provincial Museum in the 1860's and was established under an Act of the Provincial Legislature (October 1868). It has, since, evolved into a public institution with nationally significant collections that are representative of the geological and biological elements of Nova Scotia and its surrounding waters. The Museum has been able to apply its information resources and expertise to work with several other agencies in the preparation of major overview documents such as *The Natural History of Nova Scotia* (Davis and Browne, 1996a & b) which currently provide a context for the presentation of its collection-based natural history information.

This report deals, particularly, with the collection of freshwater mussels, one component of the zoological collections of the Museum. This collection has become more accessible for public use through new data-based tools such as the Museum Information Management System (MIMS).

Freshwater mussels are bivalve molluscs (Figure 1) and as such have characteristics common with marine species such as the quahog, oyster and blue mussel. The Mollusca also includes the Gastropoda which are largely snail-like, the Cephalopoda, which are squids and octopuses, and several other specialized groups.

Freshwater mussels are a group of invertebrate animals that is familiar to most people who enjoy recreational activities on lakes and streams. However, most people are unable to distinguish the eleven species (Table 1) that occur in the Atlantic provinces of Canada (a small representation of the nearly 300 species that are found in continental North America). In the current study, the native freshwater mussels (Order Unionacea) are of direct concern. Eleven species have been recorded for New Brunswick and Nova Scotia, most from the mainland. Only two species, *Margaritifera margaritifera* and *Pyganodon cataracta* have been reported for Prince Edward Island.

Mussels require clean, well-oxygenated water and are very sensitive to environmental stress. Their historic distribution and current status are of importance to both short term and long term environmental monitoring. Freshwater mussels are considered to be one of the most vulnerable groups of freshwater organisms in North America (Metcalfe-Smith and Cudmore-Vokey, 2004). This is partly due to their peculiar ecological relationship with fish. In order to reproduce, most freshwater mussels (including all Nova Scotia species) have an essential parasitic relationship with freshwater and anadromous fish. The fish carry the larvae of the mussels during the early stages of their development (Figure 2) and thus partially control their patterns of distribution. The known fish hosts and their mussel parasites for Atlantic Canada are summarised in Table 2.

Freshwater mussels were first documented in Nova Scotia by J.R. Willis (1863) and by J.M. Jones (1877) but specimens were not collected for the museum until 1895 when H. Piers, acquired the Eastern elliptio (*Elliptio complanata*). Further individual lots of specimens were acquired in 1902, 1921 and 1923, but it was in the 1940's when systematic collecting began. H.D. Athearn embarked upon several seasons of mussel surveys of Nova Scotia and New Brunswick (1946-48, 1951, 1954) and in 1950, D. Livingstone made some collections in connection with his studies of freshwater fish of Nova Scotia (Livingstone, 1951). Sampling was continued by A.H. Clarke and A. Meachem Rick of the National Museum of Canada (Athearn and Clarke, 1962; Clarke and Meachem Rick, 1963). The Museum's collection developed significantly as a result of these studies. Some specimens sent on loan to the Museum of Zoology at the University of Michigan in the 1960s are, currently, retained in that collection. Clarke (1981), an essential Canadian reference, includes the freshwater mussels of Atlantic Canada.

Miscellaneous collections were made by Museum staff in the following years. The relocation of the Museum to new quarters in 1970 provided better facilities for the development of collections, as well as full-time curatorial staff. During the next 25 years field research and collecting were carried out by the author and colleagues. This was to confirm the persistence of species previously documented and to provide more records particularly for areas of interest (e.g. in support of the programs such as Special Place Protection Act). Many new locality records were made and the general understanding of the freshwater mussels of Nova Scotia proposed by Athearn and Clarke (1962) and Clarke and Meachem Rick (1963) was supported. Several NSM Curatorial Reports summarised freshwater mussel occurrences (Grigg, 1972 and Davis, 1985) and attention was drawn to some rarer species (Isnor, 1981).

In the mid 1990's the Government of Canada in partnership with Provinces and Territories began to address the national and international concern for the maintenance of the world's biodiversity. One result of this was the Accord for the Protection of Species at Risk (1996). Freshwater mussels are included in *Wild Species 2005* and the status of a species is assessed by a species specialist sub-committee of the Committee on the Status of Endangered Wildlife in Canada ((COSEWIC) 2005). Species are prioritised annually and candidates for detailed assessment selected (Metcalfe-Smith and Cudmore-Vokey, 2004). The NSM provides information from its collection resources in support of such initiatives.

Figure 1. Shell valves of the Eastern Elliptio, *Elliptio complanata*, showing terminology used for main features of the shell. Adult, slightly reduced in size.

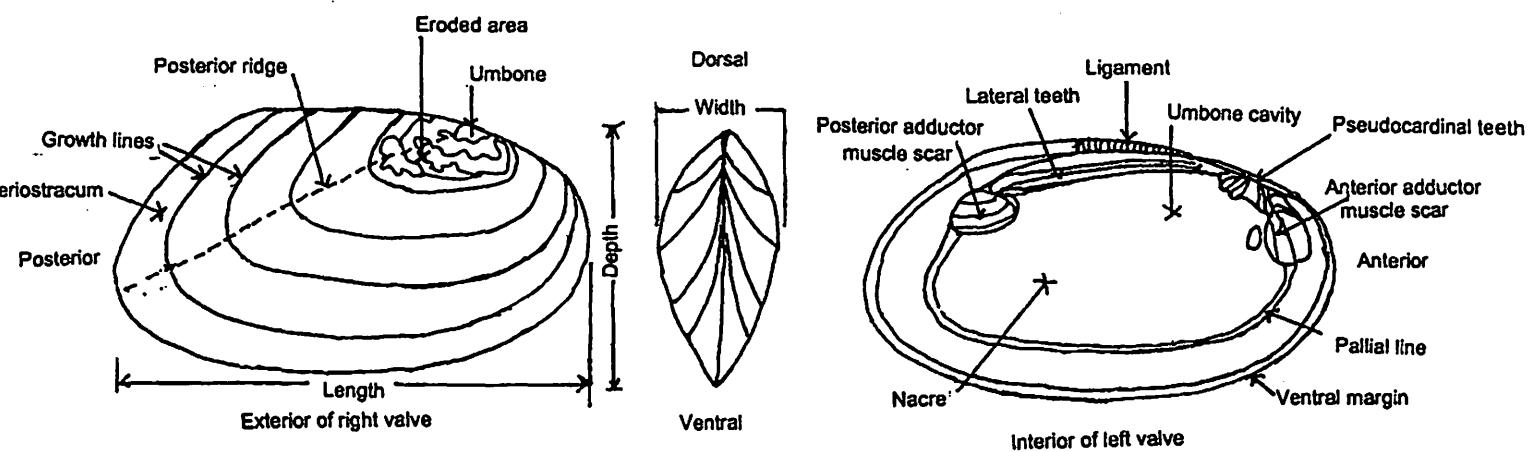

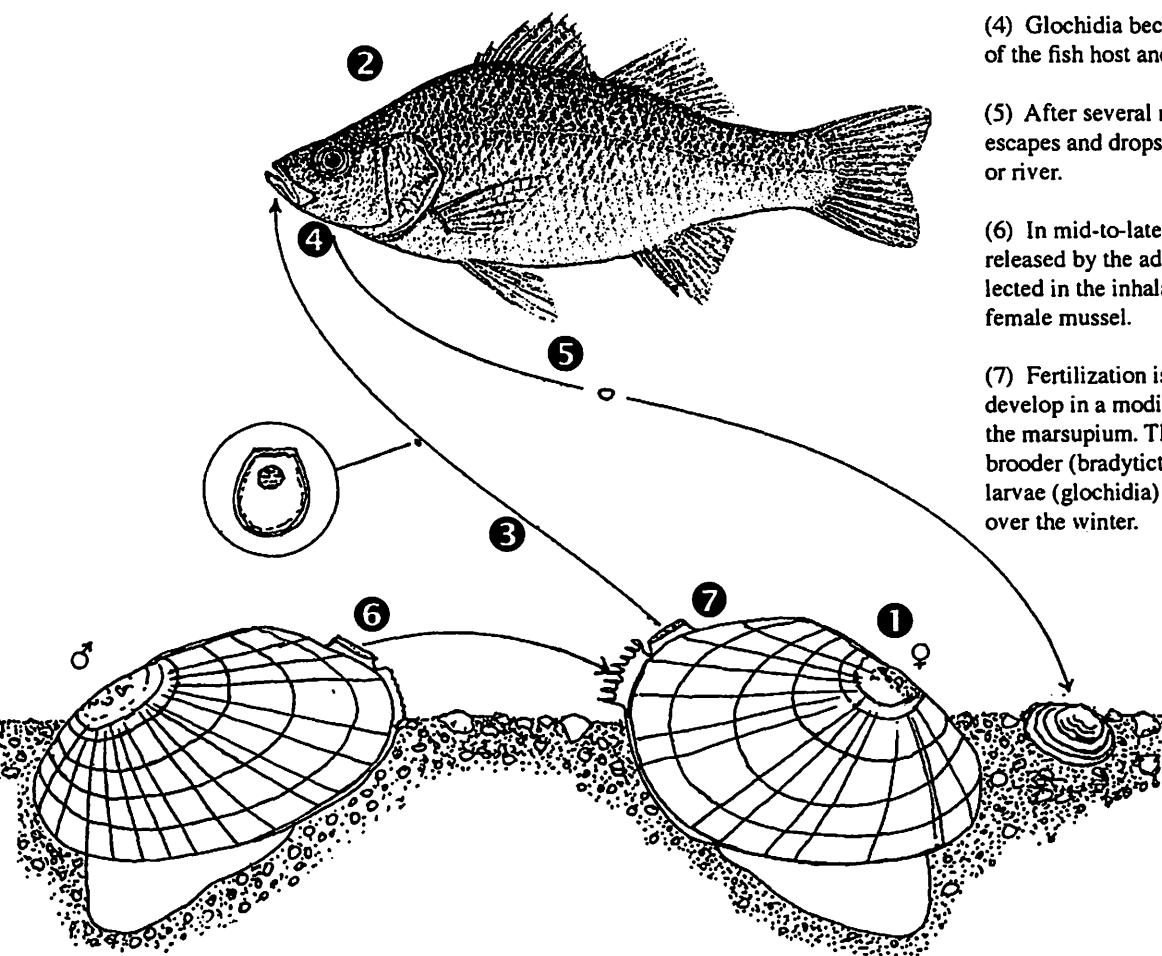

Figure 2. A typical Unionid life history as illustrate by the Eastern lampmussel (1), *Lampsilis radiata*. After Clarke (1981), Nedea et al (2000) and Wiles (1975).

- (2) White perch, *Morone americana*, is attracted to the exhalant siphon of the female mussel where glochidia are being released.
- (3) Glochidia are released in large numbers in the early summer. Each bivalve shell has a length of about 0.25mm.
- (4) Glochidia become embedded in the gills of the fish host and assume a parasitic life.
- (5) After several months the young mussel escapes and drops to the bottom of the lake or river.
- (6) In mid-to-late summer spermatozoa are released by the adult male mussel and collected in the inhalant siphon water flow of the female mussel.
- (7) Fertilization is internal and the embryos develop in a modified area of the gills, called the marsupium. This species is a long-term brooder (bradyticic) and the developing larvae (glochidia) are retained by the female over the winter.

There is concern for the future survival of freshwater mussels in Atlantic Canada in view of the severe impact of introduced Zebra and Quagga mussels in the Great Lakes region.

COSEWIC recognized the vulnerable nature of freshwater mussels globally and in Canada, and embarked upon assessments of the species in Canada. Nova Scotia is a partner in this process.

The Nova Scotia Department of Natural Resources (NSDNR) initiated extensive field studies of the distribution of native freshwater mussels in Nova Scotia through several of its Regional Offices. This survey program was comprehensive for Cape Breton Island, Northern, Eastern and Central Nova Scotia, but did not address portions of Southern and Western Nova Scotia where work still needs to be done. An overview report on the project has been published (Lockett, 2001).

The NSM is a partner in these studies and has provided training and advice, and has incorporated the resulting collections into the Provincial collection. A full list of the freshwater mussels held at the Museum is provided in this report.

The collection resource is managed to support research and education and has particular value to the understanding of climate change, support of the environmental assessment process as well as to the systematics and ecology of mussel species and their conservation status.

This Curatorial Report provides an introduction to the freshwater mussels of Nova Scotia and an interpretation of the information available in published literature and the collection of the Nova Scotia Museum. Although descriptive information is provided the report is not intended to be a field identification manual.

Table 1. Classification of Freshwater Mussels and Clams of Atlantic Canada from Turgeon *et al.* (1998) with amendments as per Clarke (1981), Burch (1975a & 1975b), and Metcalfe-Smith and Cudmore-Vokey 2004.

Class Bivalvia

Order Unionoida

Family Margaritiferidae

Margaritifera margaritifera (Linnaeus, 1758) Eastern pearlshell

Freshwater mussels

Family Unionidae

Subfamily Ambleminae

Elliptio complanata (Lightfoot, 1786)

Eastern elliptio

Subfamily Anodontinae

Alasmidonta varicosa (Lamarck, 1819)

Brook floater

Alasmidonta undulata (Say, 1817)

Triangle floater

Alasmidonta heterodon (I. Lea, 1830)

Dwarf wedgemussel

Strophitus undulatus (Say, 1817)

Creeper

Pyganodon cataracta (Say, 1817)

Eastern floater

Pyganodon fragilis (Lamarck, 1819)

Newfoundland floater

Anodonta implicata Say, 1829

Alewife floater

Subfamily Lampsilinae

Lampsilis cariosa (Say, 1817)

Yellow lamp mussel

Lampsilis radiata (Gmelin, 1791)

Eastern lampmussel

Leptodea ochracea (Say, 1817)

Tidewater mucket

Order Veneroida¹

Family Dreissenidae (invasive, not presently in Atlantic Canada)

Dreissena bugensis Andrusov, 1897

Quagga mussel

Dreissena polymorpha (Pallas, 1771)

Zebra mussel

Family Corbiculidae (invasive, not presently in Atlantic Canada)

Corbicula fluminea (Muller, 1774)

Family Sphaeriidae

Pisidium 11 species

Pea clams, Pill clams

Sphaerium 2 species

Fingernail clams

Musculium 3 species

Fingernail clams

¹ Species listed for the Order Veneroida: families Dreissenidae and Corbiculidae are well known invasive species in North America and elsewhere but have not yet been reported in Atlantic Canada. The family Sphaeriidae is a common native family including at least 16 species in Atlantic Canada. The genera *Sphaerium*, *Musculium* and *Pisidium* are well represented in Museum collections but have not been thoroughly studied in Atlantic Canada and are not included in the present study.

The Status of Nova Scotia Freshwater Mussel Populations

Distribution maps based on surveys and opportunistic collecting over a period of more than 60 years do not reflect current status of the populations of mussel species. However, they do provide baseline information for studies of populations and changes in patterns of distribution.

The *National General Status Assessment of Freshwater Mussels (Unionacea)* (Metcalfe-Smith & Cudmore-Vokey, 2004) provides the method for status evaluation. In a national program all Territories and Provinces except Prince Edward Island and Newfoundland and Labrador were able to provide assessments of the status of their mussel populations.

The information held by the NSM, including that obtained during the recent NSDNR surveys, was used as a basis for providing a general status assessment for the Province of Nova Scotia (Status Rank), for Canada (COSEWIC) and for North America (Global Status). Since a large part of Nova Scotia was included in these surveys, the published assessments are probably appropriate for most species (See Metcalfe-Smith & Cudmore-Vokey, 2004).

Status rankings for each species have been included in this report.

Methods

This study has two components, the documentation of archival resources of the collection of the NSM (pre 1999) and the collection of new data by the NSM, NSDNR and others during the period 1999-2005.

1. The Mollusca collection comprises land, freshwater and marine species both local and exotic. The largest part is preserved dry while other material is preserved in 70% ethanol. Early records are documented in ledgers, accession books and card catalogues, but these and recently acquired material are now catalogued in the Museum's database. The Museum Information Management System (MIMS) is a proprietary system developed in 1997. It is a modified multi-user, client-server system incorporating a hybrid relational and object-oriented database design. Audited data from this project are fully represented in the MIMS database.
2. NSDNR initiated a survey of freshwater mussels in Nova Scotia in 1999 following a commitment to the National General Status Assessment of Freshwater Mussels. Samples were collected in eleven counties as per the methods outlined in Maclean (1999) and Pulsifer (1999). The field-generated Mussel Survey Data forms (Appendix I i) were then used as the basis for the Nova Scotia Museum Invertebrate Data record sheets (Appendix I ii). These data were entered into MIMS with the ultimate generation of MIMS record reports (Appendix I iii).

Site information documents, both positive and negative sites and labeled collections were presented for archive at the NSM. Initial annual projects provided selected material for the collection with accompanying manuscript reports Banks (1999), Maclean (1999),

Pulsifer (1999) and Sampson and Touesnard (1999). Later, all collected material was received by the NSM and subsequently sorted and catalogued at the Museum.

An example of field data and information drawn from this for the Museum database are shown in Appendix I. Full information on all NSDNR field collections will be included in a NSDNR report (in preparation).

Results and Discussion

The catalogue of the freshwater mussels of the NSM is up-to-date as of June of 2006. The attached data shows 1083 entries, which include 919 records for Nova Scotia (Appendix II) and 164 records for other areas including both North American and exotic species (Appendix III). The Nova Scotia records are the main focus of the present study.

Early collections made in Nova Scotia, up to and including 1999 provide 338 lots. A specimen lot is a single catalogue entry. It is usually all specimens of a single species collected at the same geographic place at the same time. These include some of the earliest specimens collected in Nova Scotia, for example *Elliptio complanata* from Rawdon River in 1902, and the first scientific collections made in the 1950's by H.D. Athearn, A.H. Clarke and others. It is noted that earlier collections were made in the 19th century, but no specimens of such have been confirmed at this time. The collections made by the staff of the NSDNR and others since 1999 have added considerably to our knowledge of the distribution of these animals in Nova Scotia. A total of 581 lots of specimens was consequently added to the collection.

Figure 3 shows all freshwater mussel records for Nova Scotia summarized on a 10km² UTM grid map of the Province. The shaded circles in each grid square may be based upon one or several records for that square. This system is based on the one used in the *Atlas of the Land and Freshwater Molluscs of Britain and Ireland* (Kerney, 1999). This map is useful when it is compared with similar maps of each species particularly in Northern and Central mainland Nova Scotia and Cape Breton Island where the survey was more systematic. In the south and west however, no comparative survey has been carried out and the records are the results of random site surveys and opportunistic collecting.

Mussel distribution is related to habitats and the patterns of distribution of these habitats in the landscape. *The Natural History of Nova Scotia, Vol. 1* provides background information on the development of the landscape while *Vol. 2* describes the diverse landscape units that occur. The map of landscape units, Theme Regions (Figure 4), provides a context for the interpretation of each distribution map. It can be prepared as a transparency that can be overlain on the species maps (Figures 4-14).

In the areas surveyed, the importance of more alkaline water and soils to mussel occurrences (Region 500 -Carboniferous Lowlands) and areas where bedrock is covered with glacial till (Region 400 - Atlantic Interior and 800 Atlantic Coast), is noticeable. Areas of granite or greywacke which have thin, acid soils and acidic water have comparatively few records. Compare Units 851 and 852 (Granite Barrens) with District 870 (Till Plain). Reference to the occurrence of mussels in landscape units will be made

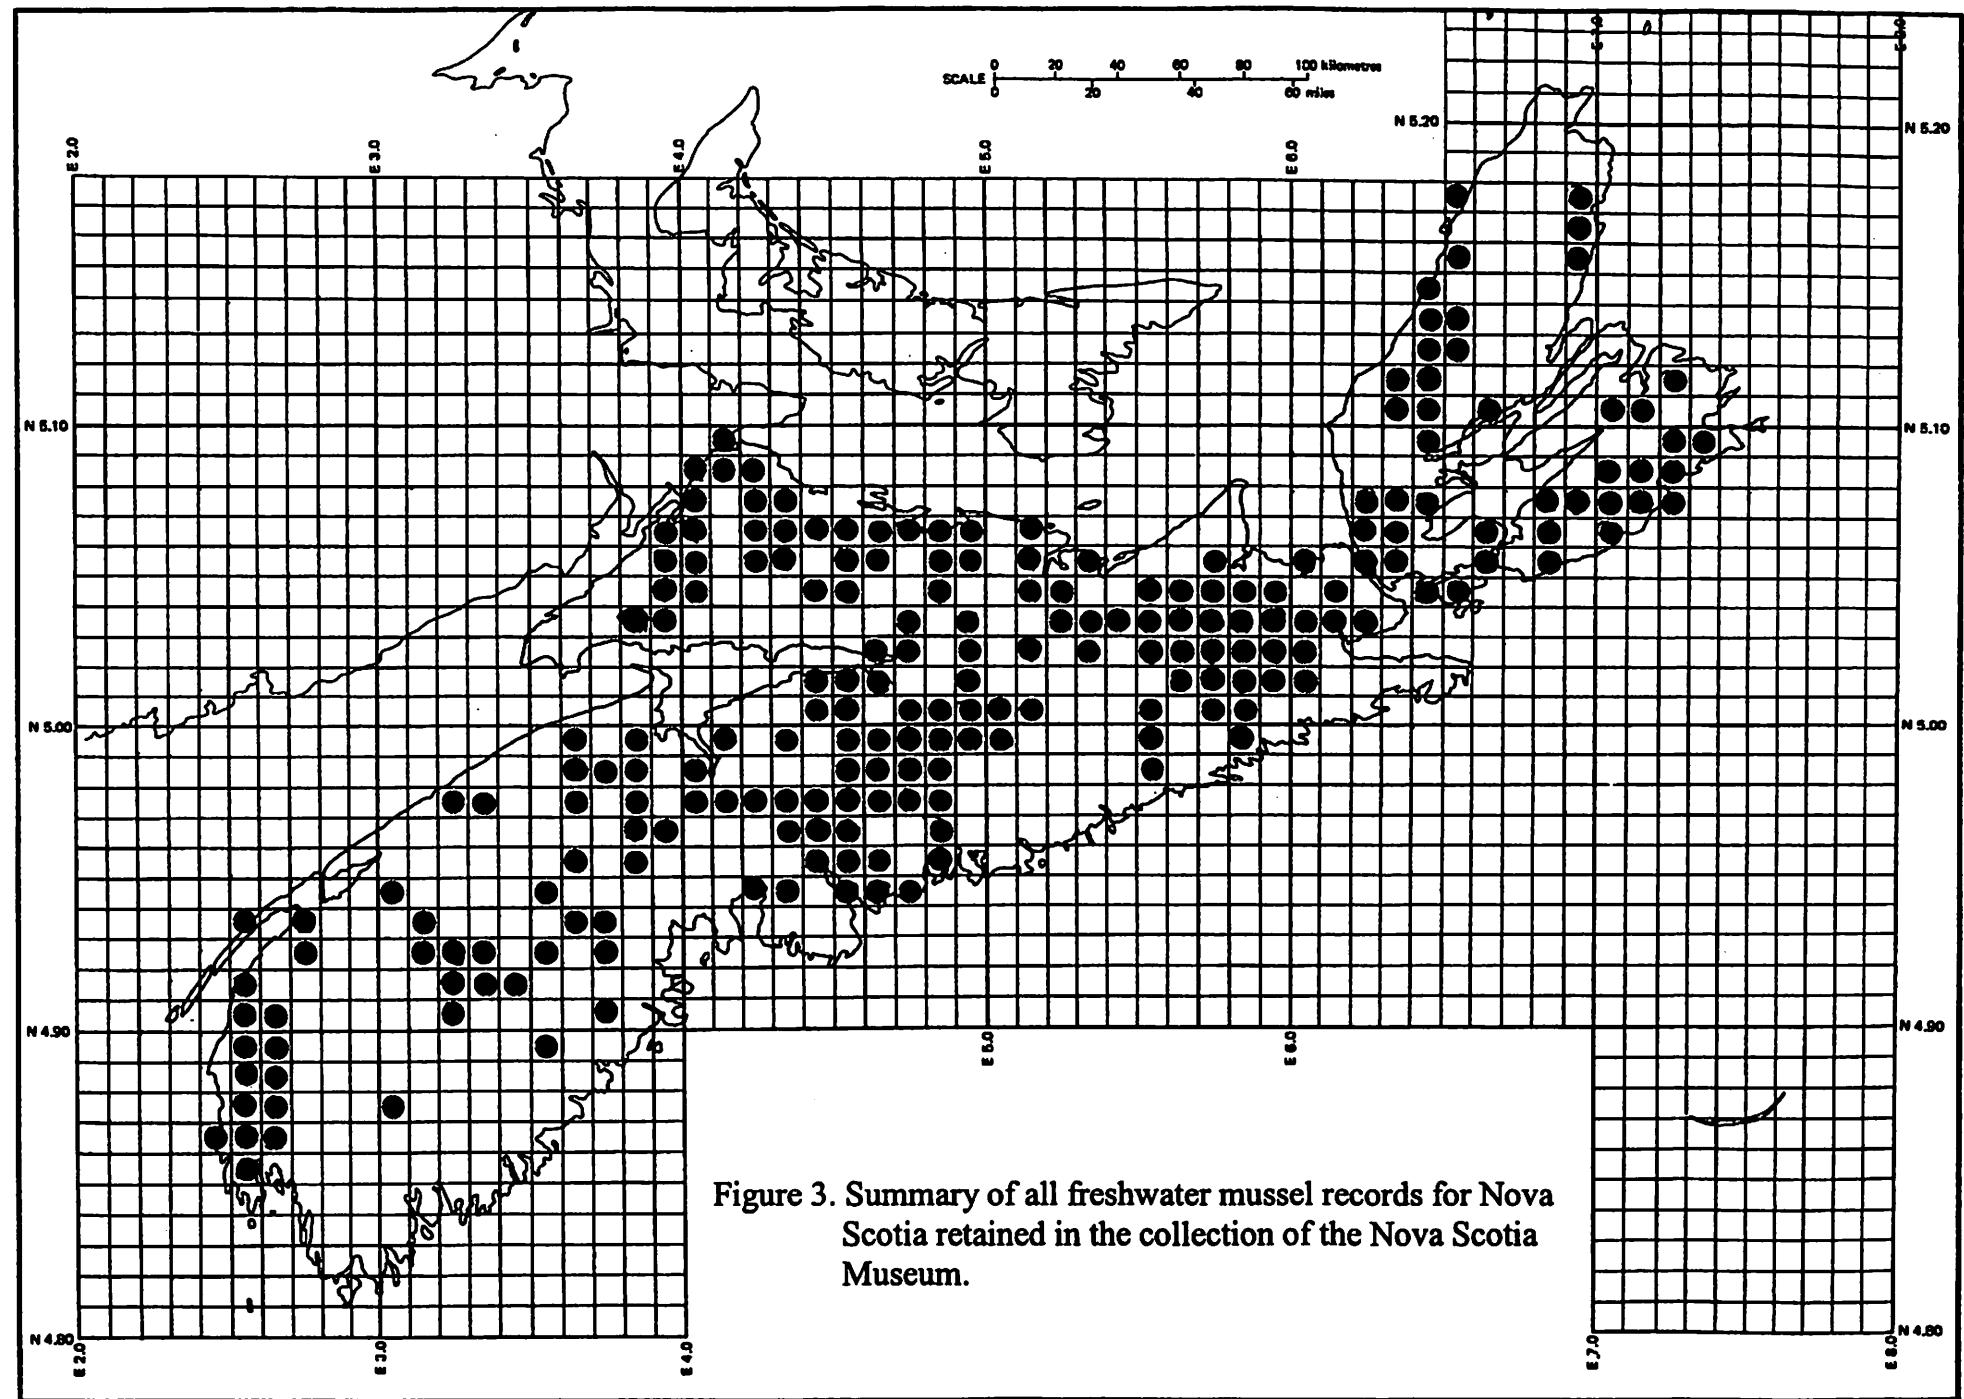

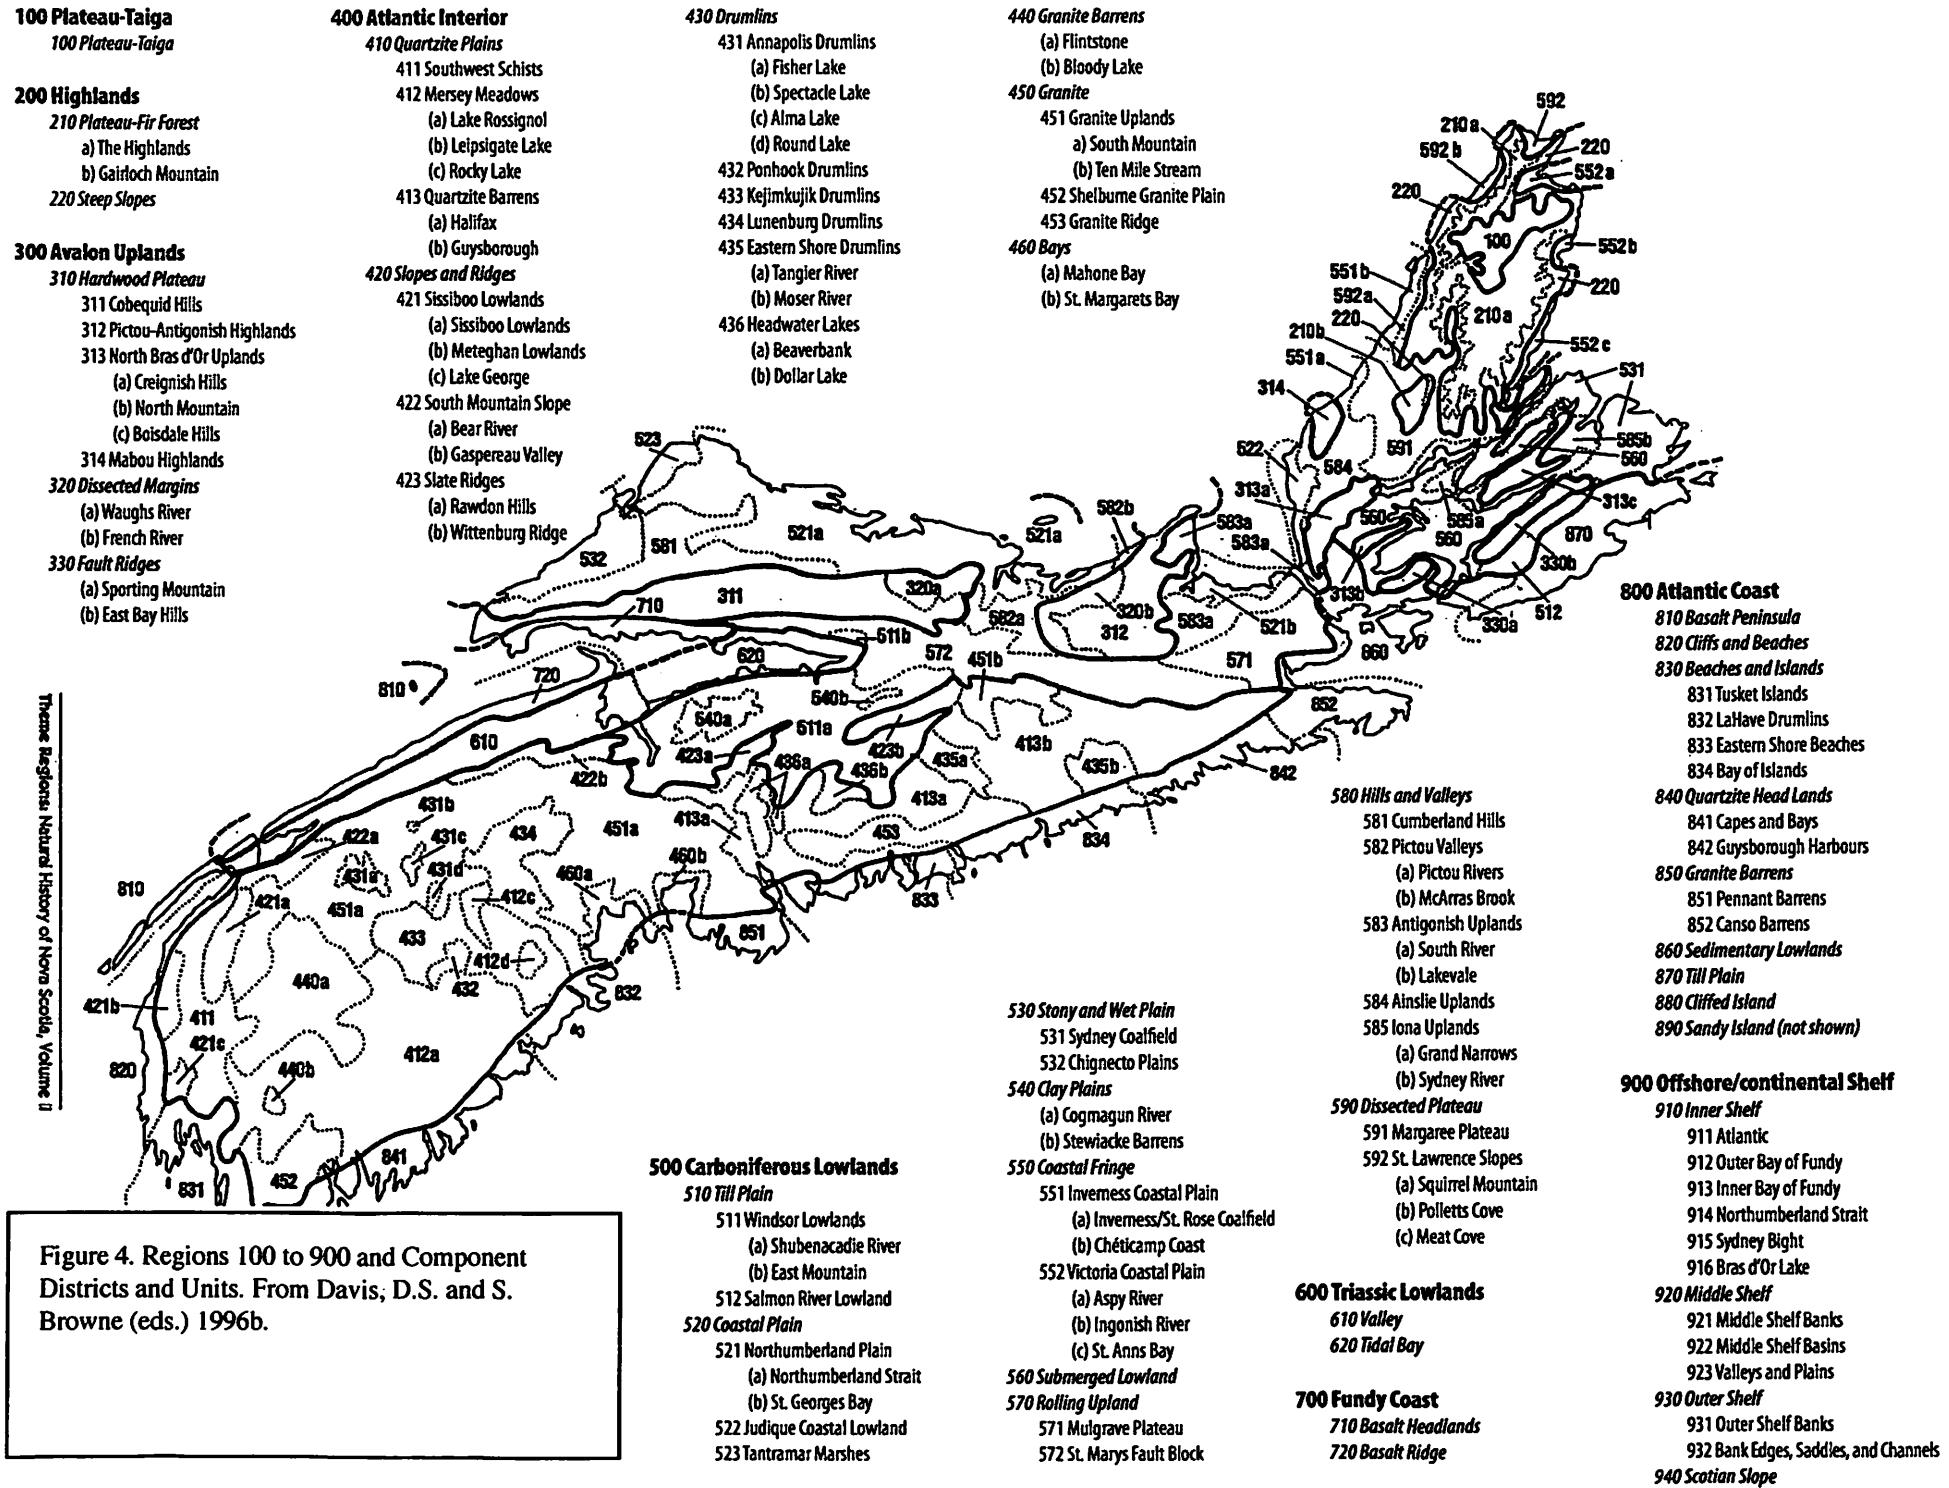

Figure 3. Summary of all freshwater mussel records for Nova Scotia retained in the collection of the Nova Scotia Museum.

in the following treatment of each species (Underwood *et al.*, 1987, Davis and Browne, 1996b).

The inventory of eleven species resulting from the work of Athearn and Clarke (1962) and Clarke and Meachem Rick (1963) remains the same after more than 40 years and their publications are the foundation references for the current studies. Recent work has provided many new records and some significant information on rare species such as *Alasmidonta varicosa* and *Strophitus undulatus*. *Alasmidonta heterodon* has never been reported from Nova Scotia, though small potential for an occurrence remains. The only known Canadian population of this species was in southern New Brunswick but this has been determined by COSEWIC to be extirpated (Hanson and Locke, 2000). The Newfoundland floater, *Pyganodon fragilis*, is not clearly distinguished in Nova Scotia although some specimens are considered to be hybrids with the Eastern floater, *Pyganodon cataracta* (Kat and Davis, 1984). In the present survey only *P. cataracta* is reported, but specimens are available for re-examination. It should also be noted that specimens of *Pyganodon* from about 84,000 years B.P. pre-Wisconsinan interglacial deposits at Milford Quarry, Nova Scotia (Godfrey-Smith *et al.*, 2003) are also available for examination in the palaeontology collection of the NSM.

Information on ten species of freshwater mussels that occur in the Maritime Provinces is provided below. The species are presented in systematic order as found in Table 1.

***Margaritifera margaritifera* (Linnaeus, 1758)**

Eastern pearlshell

Plate I: 1 and 2; Figure 5: Summary of Records in Nova Scotia

First recorded in Nova Scotia as “*Alasmidonta* (sic) *margaritifera*” by J.R. Willis (1863), from rivers in Annapolis County and the Sackville River. J. Matthew Jones later reported it as “*Margaritana arcuata*, St.” (Jones, 1877). However, it was not until the late 1940’s that H.D. Athearn carried out the first province-wide study that resulted in 23 confirmed locality records and 13 specimen lots for the NSM collection (Athearn and Clarke, 1962). This work was continued by Clarke and Meachem Rick (1963) who reported *Margaritifera margaritifera* from 17 additional sites in Nova Scotia. Additional records from some new stations were made by NSM staff and others prior to the recent NSDNR survey 1999-2004. The NSDNR survey did not include areas of southwest Nova Scotia and there remain deficiencies in information about *M. margaritifera* in this area. Currently the NSM has 145 specimen lots from Nova Scotia, 9 lots from New Brunswick and 2 lots from Newfoundland and Labrador.

Several authors have noted that *M. margaritifera* occurs in Eastern North America and Northern Europe. However, a recent study of DNA by Huff *et al.* (2004) reviewing the classification on the genus *Margaritifera* has demonstrated that the European and North American populations may be different species. Nova Scotia material has been collected by the NSM and sent for study.

The size, shell shape and colour conform to descriptions in Clarke (1981), Nedeau *et al.* (2000) and Burch (1975a). The bivalve shells reach up to 150mm in length and 65mm in

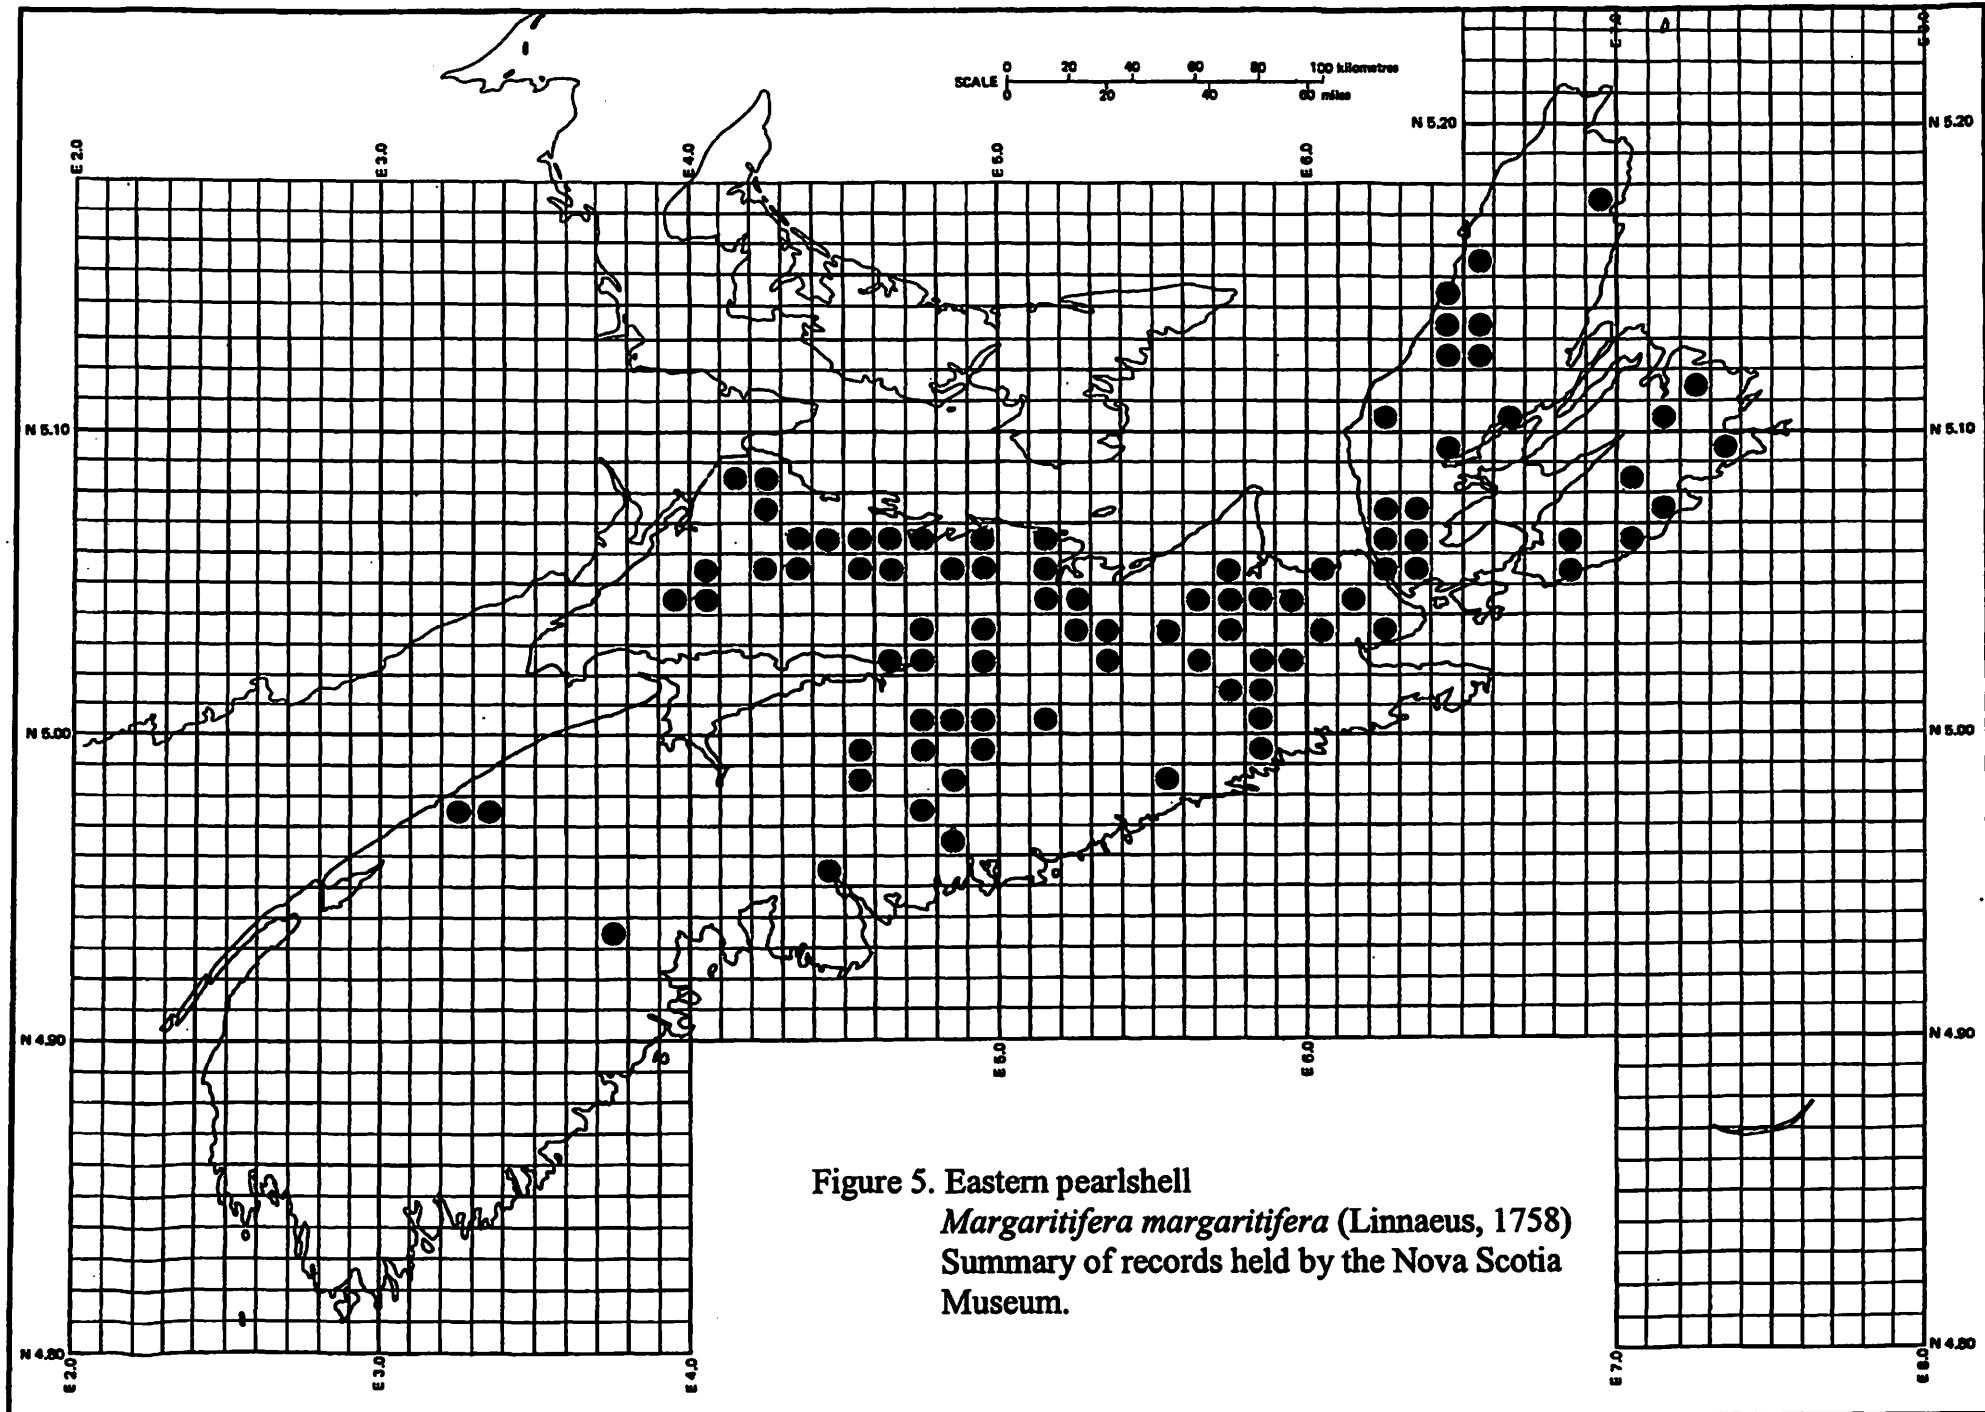

Figure 5. Eastern pearlshell
Margaritifera margaritifera (Linnaeus, 1758)
Summary of records held by the Nova Scotia
Museum.

height with a straight or slightly concave lower margin. The colour of the periostracum is brown to black and the inside of the shell is whitish with a series of microscopic pits characteristic of the Margaritiferidae. There are pseudocardinal teeth but no lateral teeth.

This species is found from Pennsylvania and New York, north through the Maritime Provinces, both sides of the lower St. Lawrence River and Gulf, Anticosti Island and Newfoundland and southern Labrador. In Nova Scotia it is mainly found in central and northern areas with records from many rivers, but rarely in the south with a few records from the Annapolis, Nictaux and LaHave (North Branch). The lack of records from the south may be due to incomplete survey effort or to adverse water quality (acidification) or other factors. The host fish for *M. margaritifera* are salmonids; Atlantic salmon, Brown and Brook trout (See Table. 2), which are sensitive to acid waters.

The common habitat for the Eastern pearlshell is flowing water of rivers and streams with mud, sand, gravel or stony bottom substrate. It is reported mainly from "soft waters" low in calcium in other parts of the range (Strayer, 1993), but also in some hard water areas in Nova Scotia.

Currently rated by COSEWIC (2006) at 4 "secure" nationally and 3 "sensitive" in Nova Scotia, due to potential effects of acid precipitation. (Nova Scotia General Status "Yellow")

***Elliptio complanata* (Lightfoot, 1786)**

Eastern elliptio

Plate I: 3, 4 and 5; Figure 6: Summary of Records in Nova Scotia

First recorded for Nova Scotia by J. R. Willis in 1863 as "*Unio complanatus*, Lea. Common to most lakes in Nova Scotia.". Since that time many records of *Elliptio complanata* have been made including those by Athearn and Clarke (1962) and Clarke and Meachem Rick (1963), as well as those of the recent NSDNR survey. These studies and many others contributed specimens to the NSM collection which currently has 300 specimen lots from Nova Scotia and 30 from New Brunswick, Ontario and the United States.

The colour and morphology of the species in Nova Scotia conforms to published descriptions (Clarke, 1981 and Nedeau *et al*, 2000) See Plate 1. Quite variable in form but typically elongate, rectangular and rounded anteriorly, truncated posteriorly and somewhat laterally compressed. The exterior is unsculptured and has a brown to black periostracum with conspicuous annual growth interruptions. Some juveniles and adults from sandy substrates are lighter in colour and may show distinct rays running from the umbones to the ventral margin. The pearly interior of the shell is usually purple to white in colour. The hinge teeth are well-developed with pseudocardinal teeth, one in the right valve and two in the left. There is one lateral tooth in the right valve that articulates with two in the left valve. There are shallow anterior and posterior adductor muscles scars. It was noticed that the specimens with rays in the periostracum associated with a sandy substrate are more common at some locations. This has caused some confusion with the Eastern lampmussel, *Lampsilis radiata*, for example at Lake Ainslie (MacLean, 1999).

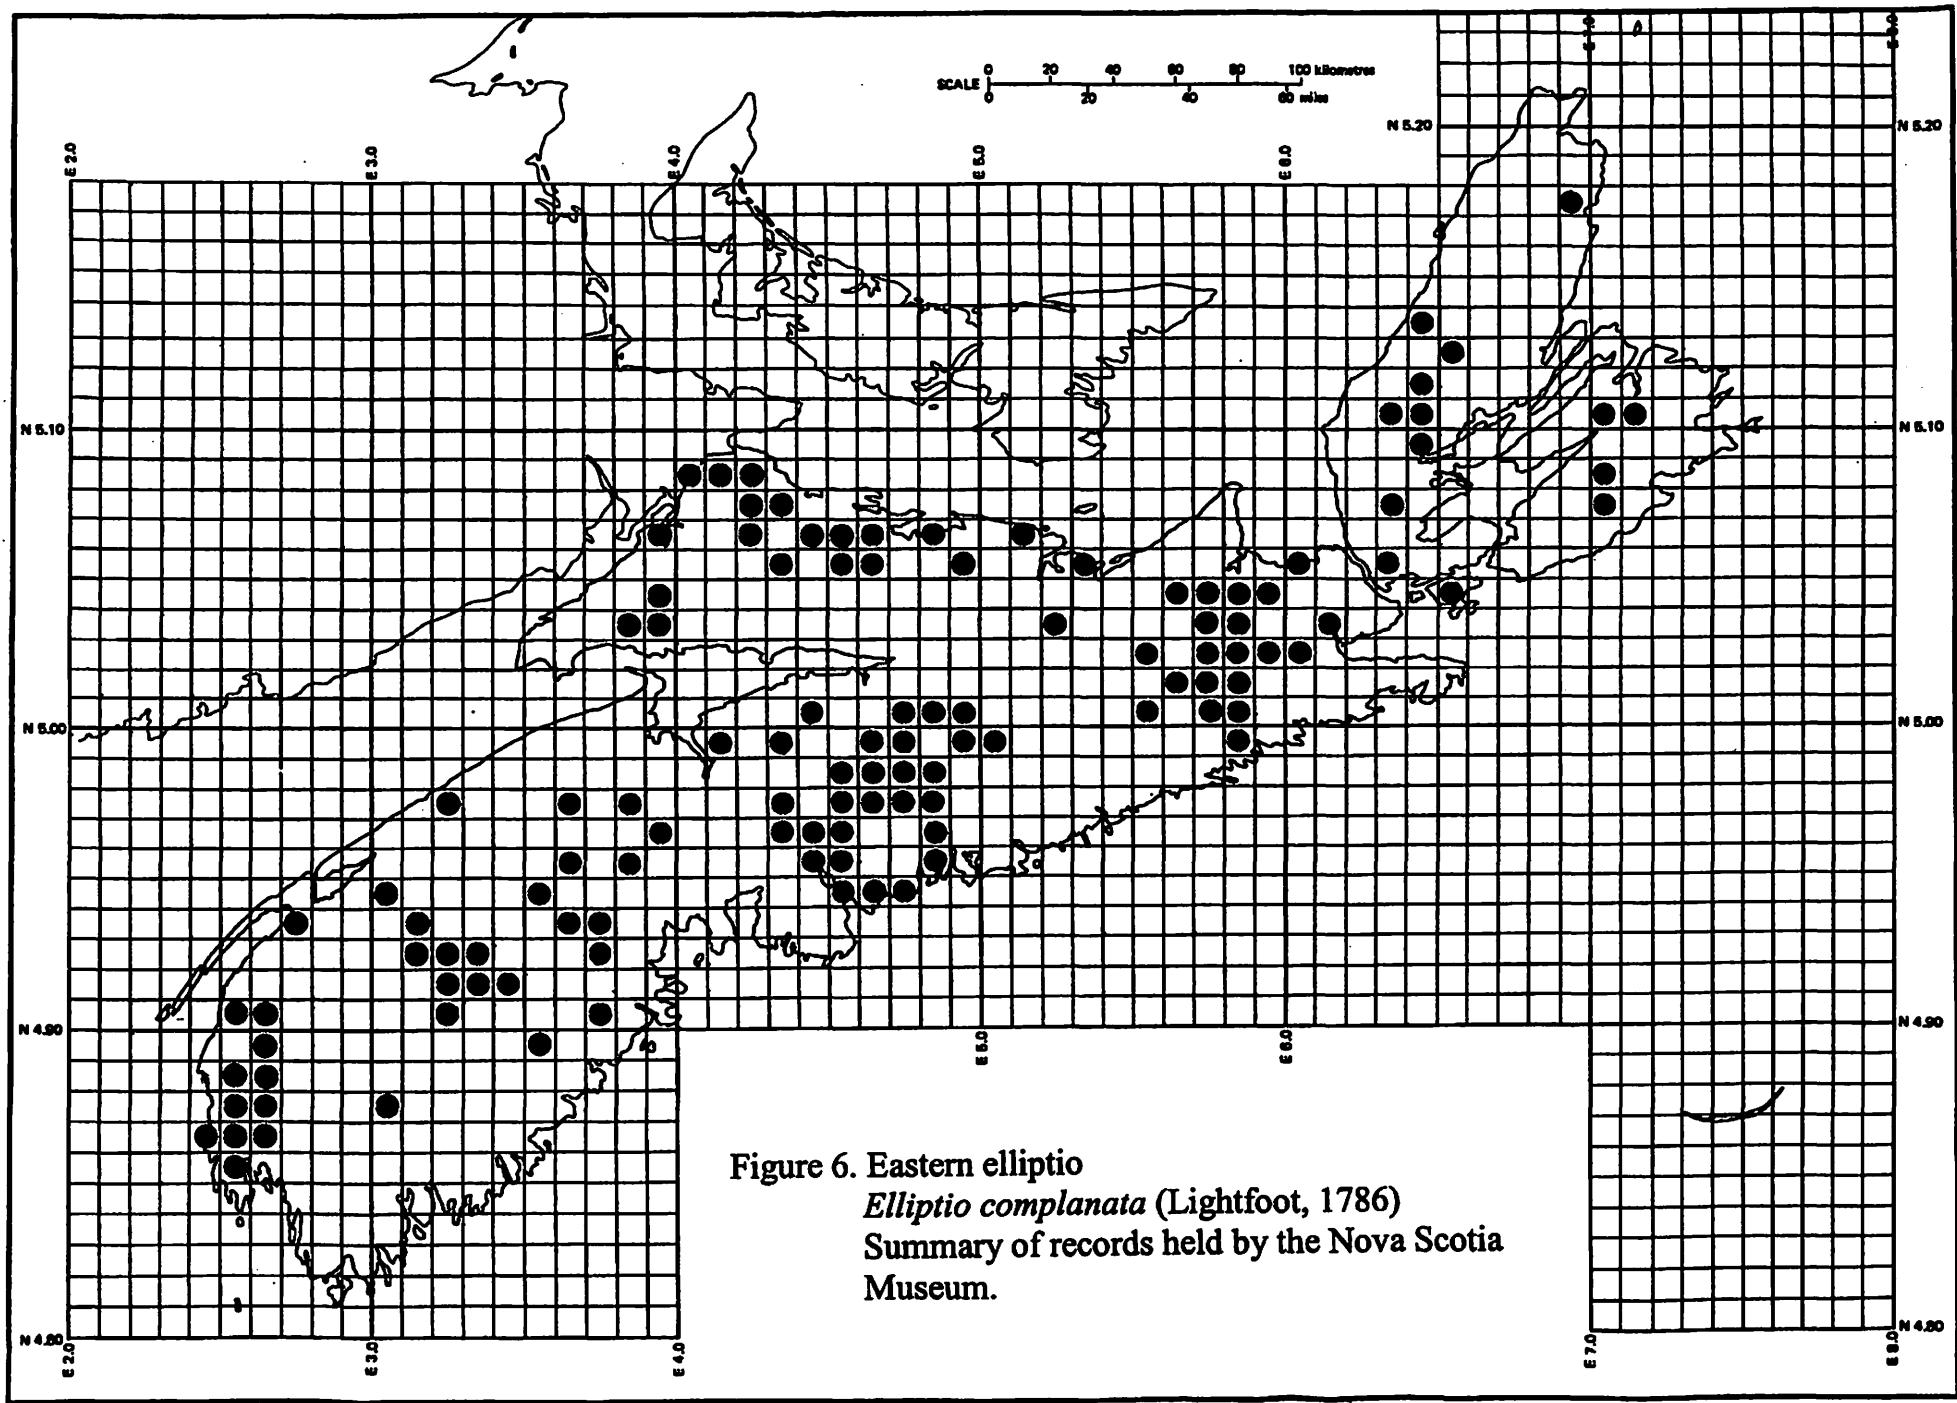

Figure 6. Eastern elliptio
Elliptio complanata (Lightfoot, 1786)
Summary of records held by the Nova Scotia
Museum.

The Eastern elliptio is found from the Atlantic drainage of Georgia, north to the eastern and northern shores of the Great Lakes. In Canada it occurs in eastern Ontario and southern Quebec, New Brunswick and Nova Scotia. It is not found in Prince Edward Island or Newfoundland and Labrador. In Nova Scotia this species has been commonly found through the Province and particularly in fertile river basins such as the Margaree, St. Marys, Musquodoboit, Shubenacadie, Stewiacke, LaHave, Mersey and Annis Rivers. The common habitat is the shallows of lakes and river backwaters (out of the main current), found both in bare sand or sandy mud and amongst littoral vegetation. It is apparently tolerant to "pollution" from street runoff as it is found in many urban lakes and ponds, e.g. Dartmouth lakes.

Mussels have been recorded up to 16 years of age with a shell length of 12.0cm (Metcalfe-Smith and Green, 1992).

The confirmed fish hosts for glochidia of *E. complanata* are Yellow perch and Banded killifish (See Table. 2).

Currently (2006) rated by COSEWIC nationally: 4, "secure" and in Nova Scotia: 4, "secure" (Metcalfe-Smith and Cudmore-Vokey, 2004). (Nova Scotia General Status "Green")

***Alasmidonta varicosa* (Lamarck, 1819)**

Brook floater

Plate I: 6 and 7; Figure 7: Summary of Records in Nova Scotia

One of the earliest Nova Scotia records of this species and certainly the first lot in the NSM collection was made by H.D. Athearn in 1946 from the St. Mary's River in Guysborough County. Athearn and A.H. Clarke reported it found in only four localities in their 1962 publication. *Alasmidonta varicosa* was obviously rare but widely distributed in Nova Scotia. During the early 1970's D.S. Davis and other staff of the Nova Scotia Museum opportunistically investigated known sites for freshwater mussels and *A. varicosa* was confirmed at two new localities; in the Wallace River, Cumberland County and East St. Mary's River, Guysborough County. However, it was not until the 1999-2002 NSDNR project that an intensive freshwater mussel survey was undertaken. As a result several new records and new Museum specimens were obtained. The lots are included in the catalogue and all known records are summarized in Figure 5. The Nova Scotia Museum has a total of 12 lots; 9 from Nova Scotia and 3 from New Brunswick.

The specimens all conform to the description by Clarke (1981). The shell is up to 70mm long, 40mm high and rather inflated at the posterior end. The ventral margin may be flat or concave. The exterior is smooth except for some weak sculpture on the posterior slope, with ridges crossing the lines of growth. The periostracum is yellowish, greenish or brownish to black, with numerous dark rays best seen in young specimens. The interior nacre is variable, coloured bluish-white but with additional pinkish-white and orange. Pseudocardinal teeth are present but poorly developed and there are no lateral teeth.

The range is the Atlantic slope drainage from South Carolina north to New Brunswick and Nova Scotia. In Nova Scotia the occurrences are sporadic and only known from a few watersheds in northern and central parts of the Province; Wallace River, Matatall

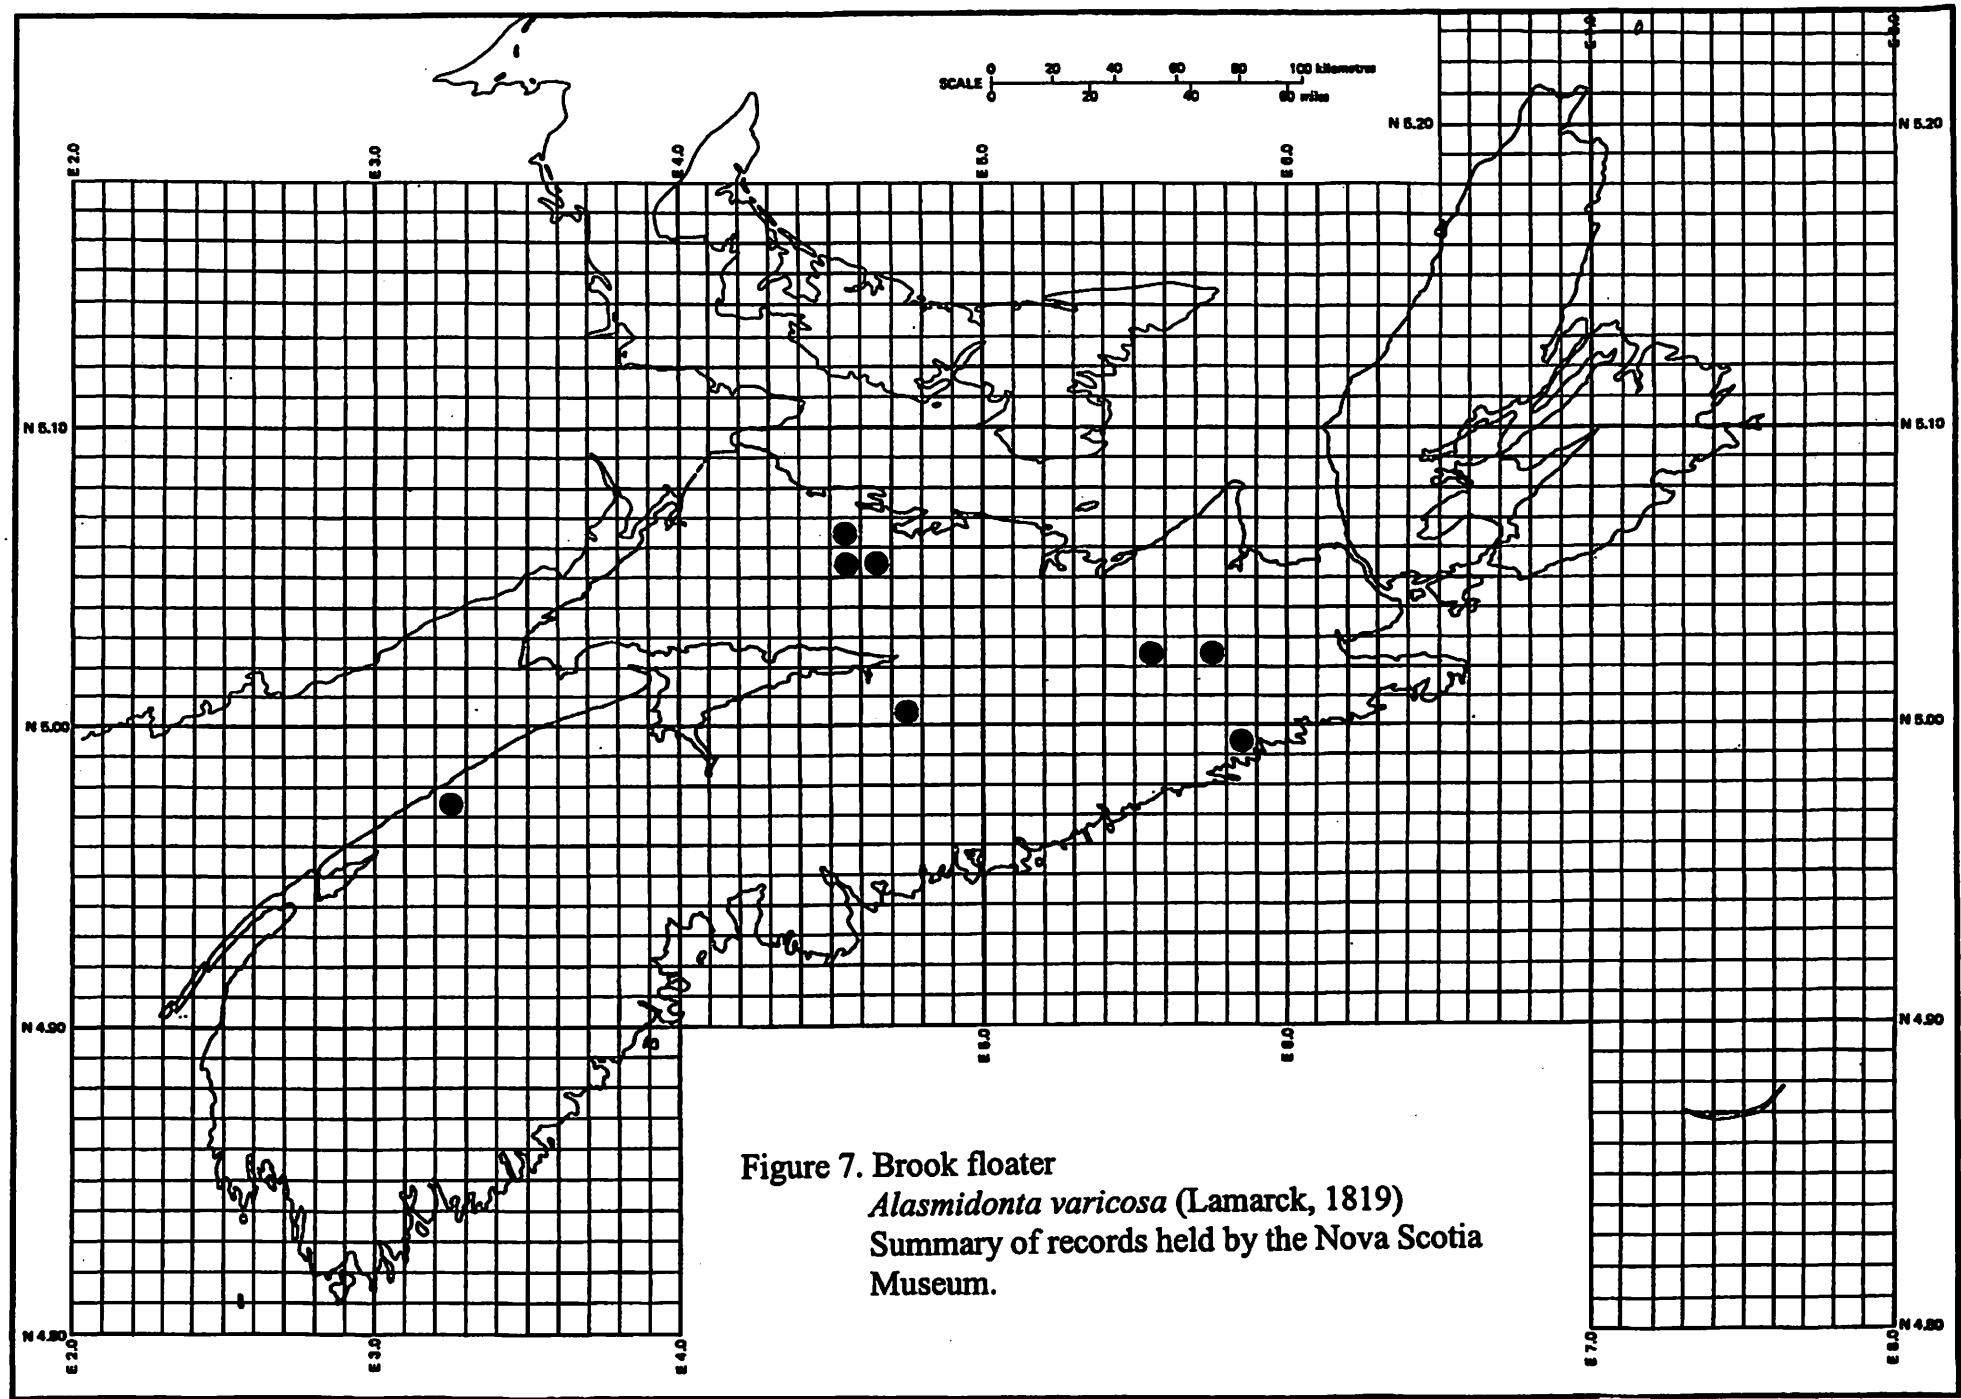

Figure 7. Brook floater
Alasmidonta varicosa (Lamarck, 1819)
Summary of records held by the Nova Scotia
Museum.

Lake, St. Mary's River, Lochaber Lake, Eden Lake, Stewiacke River and Annapolis River. There are no records for southern Nova Scotia or Cape Breton Island.

Both river and lake habitats are reported, with bottoms of rock and gravel. In the areas occupied, waters have a pH above 5.4. Host fish in Nova Scotia are most likely Golden shiner, Blacknose dace, and Yellow perch (See Table 2). *Alasmidonta varicosa* is a long-term brooder with brooding lasting from August to the following May.

Status rank has been determined by COSEWIC as Level 3 "sensitive", both nationally and in Nova Scotia, but Level 2 "may be at risk" for New Brunswick. (Nova Scotia General Status "Yellow")

***Alasmidonta undulata* (Say, 1817)**

Triangle floater

Plate I: 8 and 9; Figure 8: Summary of Records in Nova Scotia

Athearn and Clarke (1962) have provided records of this species from central Nova Scotia and some of their specimens are in the NSM collection. They suggest the report by J.R. Willis (1863) of "Unio ...(?)" from "Dartmouth Lakes" was probably that of *Alasmidonta undulata*. Collections made by the NSM in 1987 confirm the presence of this species in Lake Banook, Dartmouth and support the view that Willis made the first record of *A. undulata* for Nova Scotia. The NSM also has an unpublished record from Rawdon River, Halifax County made in 1902 by H. Piers. Other collections were made by N. S. Museum staff between 1869 and 1987. Between 1999 and 2004 the survey of central and northern areas of Nova Scotia, carried out by NSDNR and supported by NSM personnel covered all of Cape Breton Island and Central and Northern Nova Scotia. The Museum collection has 32 specimen lots from Nova Scotia as well as five lots from New Brunswick collected by H. D. Athearn (1946-51).

The morphology conforms to that described by Clarke (1981). The adult shell is thick, triangular in shape and up to 75mm long. It has a smooth external surface, except for umbone sculpture. The periostracum is coloured yellowish, greenish or reddish-brown with darker rays that may be obscured by black colouration in older specimens. The hinge teeth are well developed and include pseudocardinals, one in the right valve and two in the left. Lateral teeth are vestigial or absent. The interior nacre is whitish to bluish coloured. A shell length of 50mm could be achieved in about 7.5 years (Metcalfe-Smith, J.L. and R.H. Green, 1992).

This species is found in the Atlantic drainage from Florida north to New Brunswick and Nova Scotia and to the St. Lawrence River below Lake Ontario. In Nova Scotia *A. undulata* has a patchy distribution in rivers draining directly to the Bay of Fundy or Atlantic Ocean. It is more common than originally thought with records now for Richmond, Inverness, Antigonish, Cumberland, Hants and Halifax counties. Southern and western Nova Scotia remains inadequately surveyed. Important centres of population are River Inhabitants, Loch Katrine, Copper Lake, Musquodoboit River, Nine Mile River, Shubenacadie headwater lakes, Dartmouth lakes, Stewiacke River, Kennetcook River, Newville Lake and River Hebert.

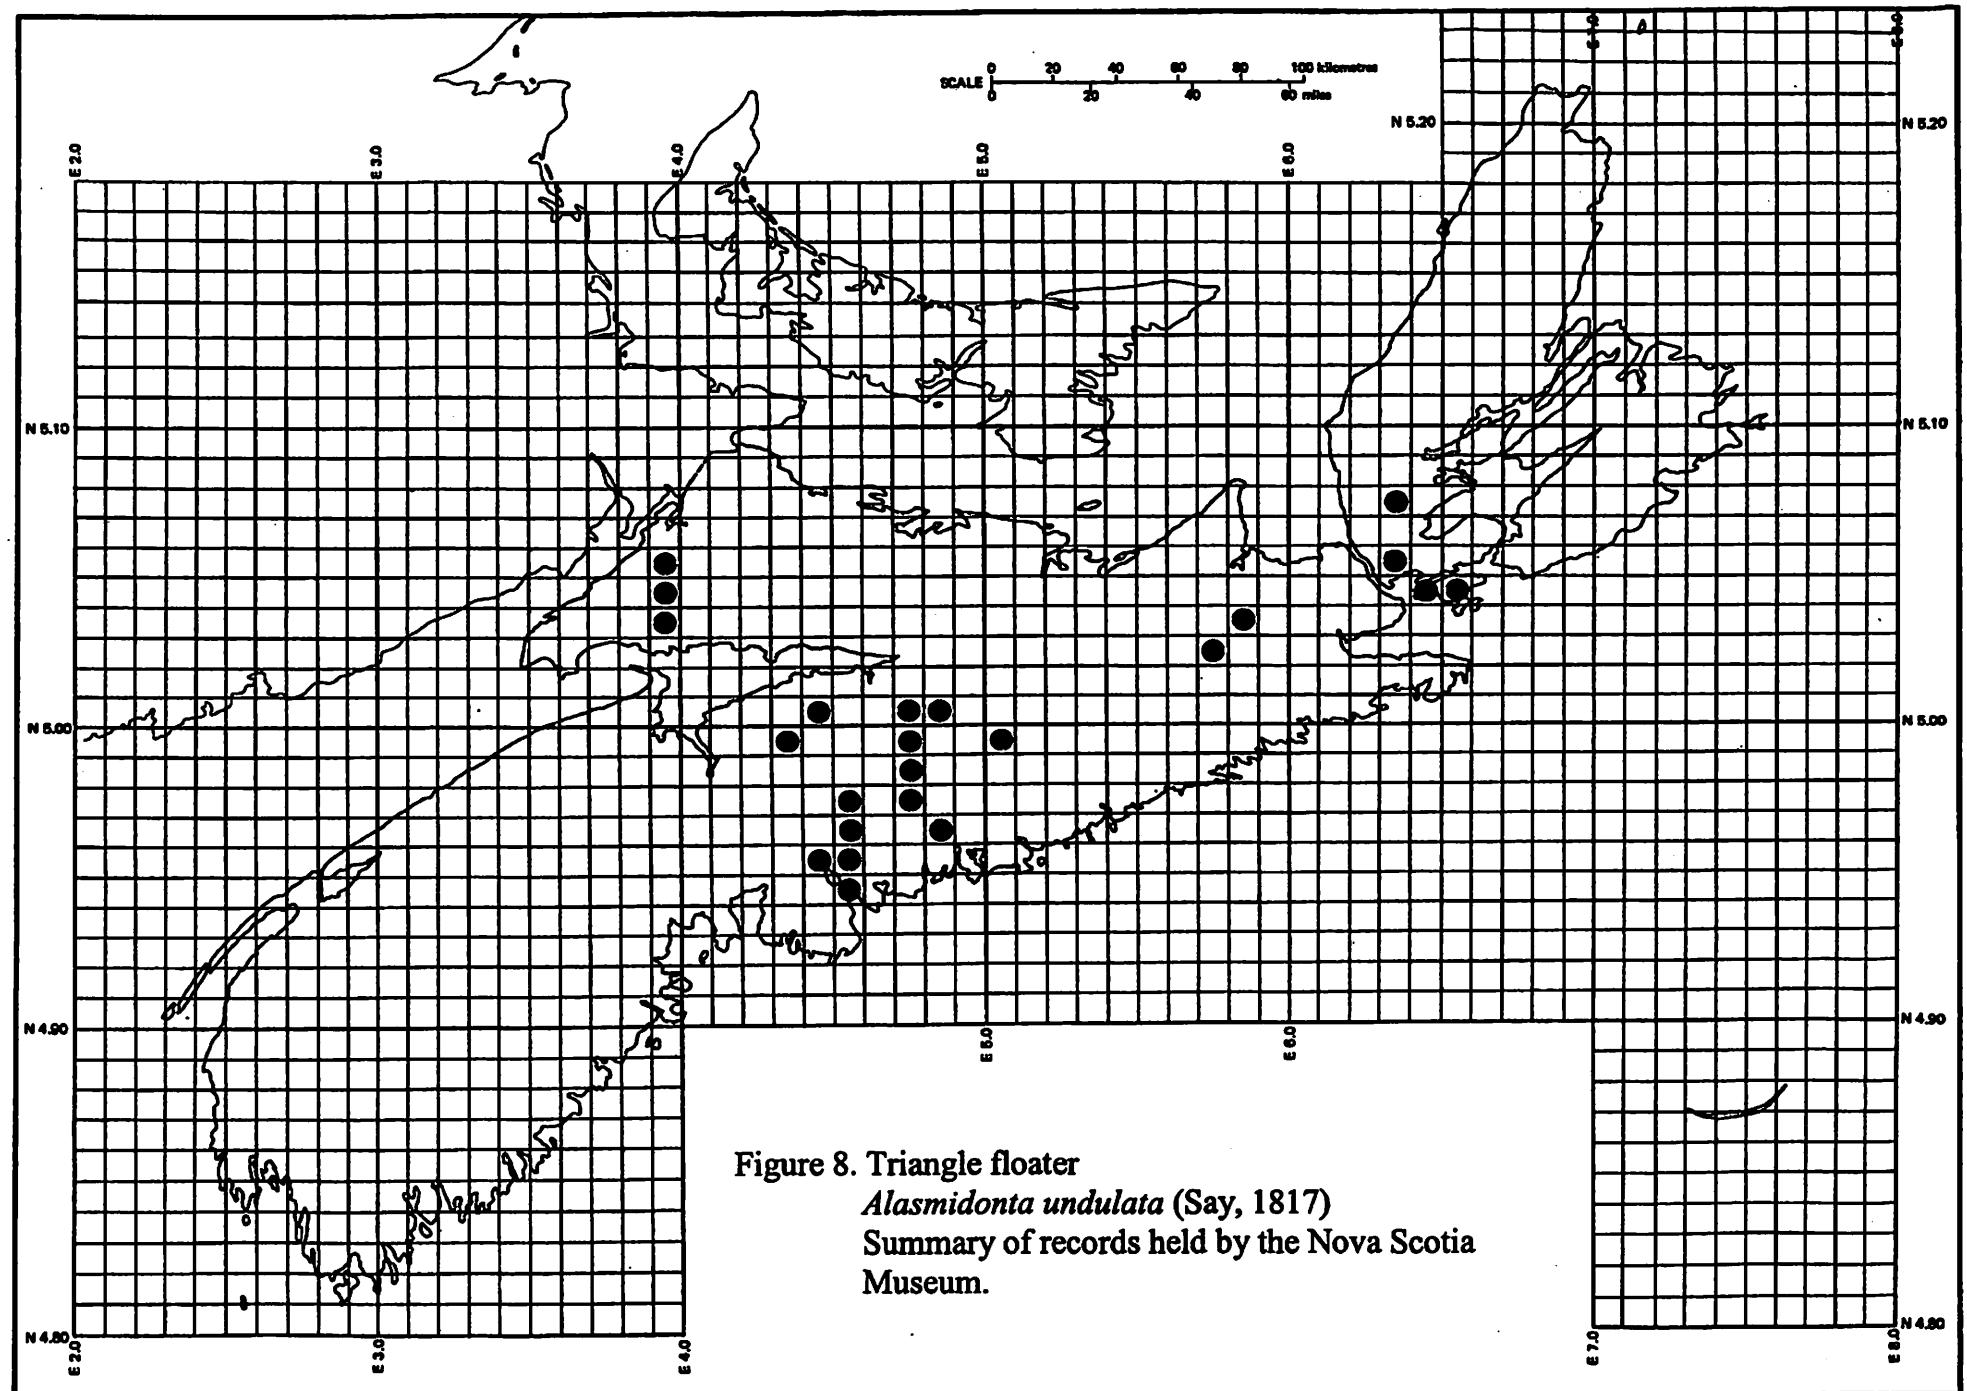

Figure 8. Triangle floater
Alasmidonta undulata (Say, 1817)
Summary of records held by the Nova Scotia
Museum.

Alasmidonta undulata makes use of river, stream and lake habitats with rock, gravel, sand or mud substrates and may also require water with pH above 5. Host fish are reported to be Common shiner, Blacknose dace and White sucker (See Table 2.).

Currently (2006) rated by COSEWIC nationally as 4, "secure" and also at 4 "secure" for Nova Scotia. (Nova Scotia General Status "Green")

***Strophitus undulatus* (Say, 1817)**

Creeper

Plate II: 12 and 13; Figure 9: Summary of Records in Nova Scotia

Strophitus undulatus was first reported for Nova Scotia by H.D. Athearn (Athearn and Clarke, 1962) from Tidnish River in Cumberland County (c. 1960). Clark and Meachem Rick (1963) collected this species only in the Shinimicas River and at Big Lake, both in Cumberland County. These sites were visited by NSM staff in the 1970's-1990's but no additional specimens were found. The recent survey by NSDNR also did not produce any records from these sites but a population was discovered at a new site, Vickery Lake, near Oxford in Cumberland County. Many other sites visited in this area did not generate any additional records. The NSM has two specimen lots from Vickery Lake in its collection.

Strophitus undulatus is a small to medium size mussel, less than 70mm in length in Nova Scotia specimens. The valves are fairly flat and thin with prominent growth lines. The periostracum is light coloured and sometimes rayed in young specimens but dark brown to black in older specimens. The hinge teeth are rudimentary or lacking. The nacre is white or bluish-white with characteristic dull yellow or green in the umbo cavity. Descriptions and illustrations of this species are given by Athearn and Clarke (1962), Clarke (1981) and Nedea *et al.* (2000).

Because this species is rather lacking in strong characters it can readily be confused with *Elliptio*, *Alasmidonta* or *Anodonta* species.

The range of this species is broad from the Nelson River and Red River in the north, through Mississippi-Ohio Rivers south to Texas and east into Pennsylvania and Tennessee. In the east it occurs in the Atlantic drainage from South Carolina, north to Nova Scotia and the Upper St. Lawrence and Great Lakes. In Atlantic Canada its range is very limited. There is a population in southern New Brunswick, as well as several small populations in Cumberland County, Nova Scotia. All known Nova Scotia localities are in Northumberland Strait drainage; Pugwash River, River Philip, Shinimicas River and Tidnish River; *Natural History of Nova Scotia* Units: 521, Northumberland Plain and 523, Tantramar Marshes.

Clarke (1981) states that the habitats are mainly rivers and creeks and Nedea *et al.* (2000) report that *S. undulatus* only occurs in rivers and streams in Maine. Strayer (1993) has determined that "non-tidal, hydrologically stable streams" are most suitable. Two of the Nova Scotia localities are in small streams and two are in lakes. Slow flows, silty-sand bottom and sparse vegetation are reported as preferred habitats.

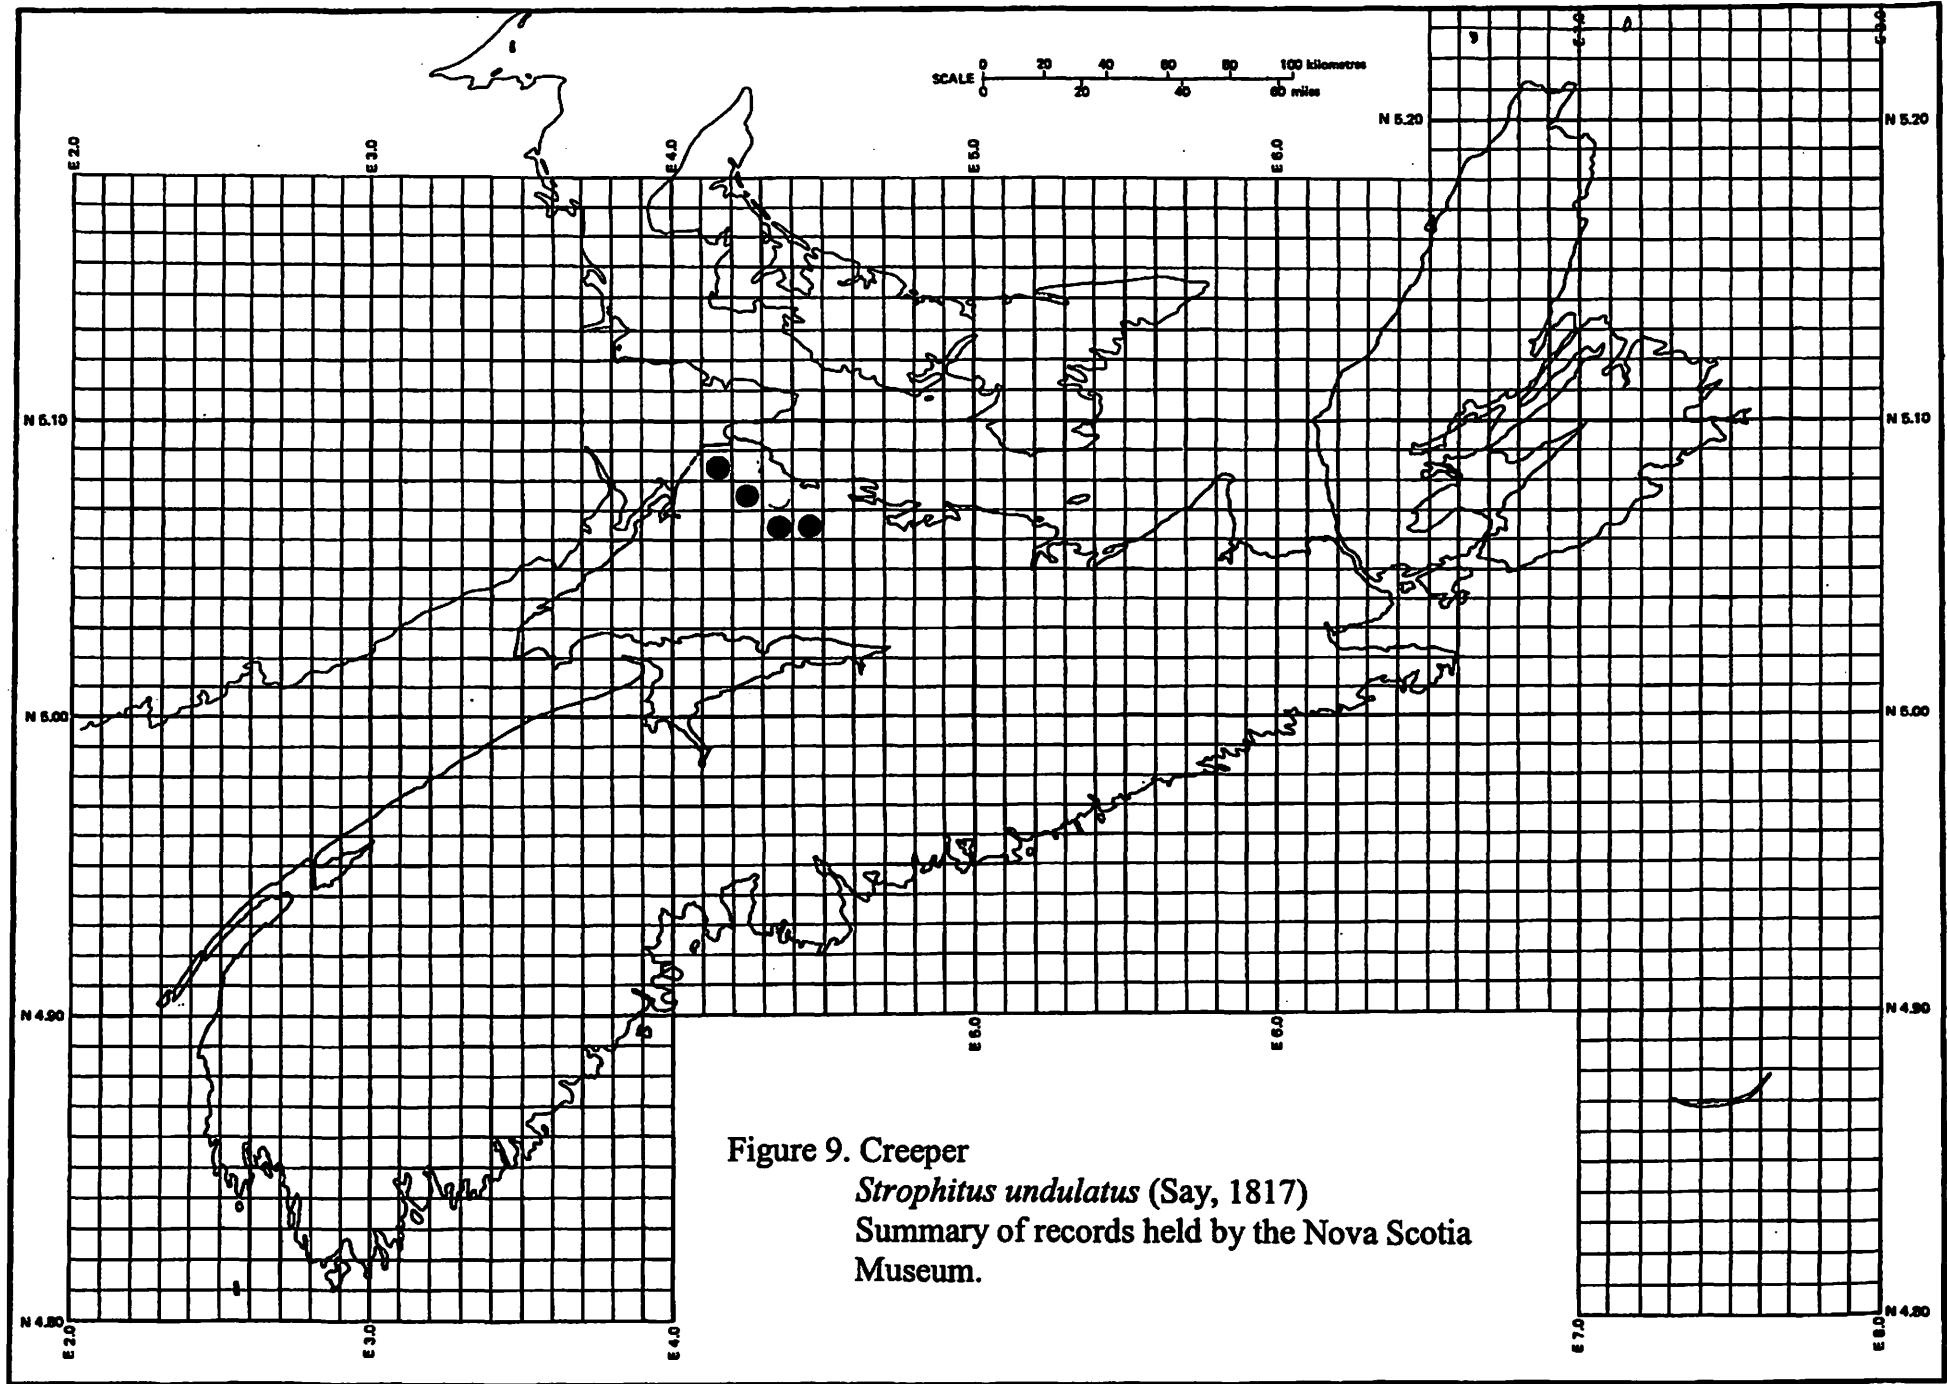

Figure 9. Creeper
Strophitus undulatus (Say, 1817)
Summary of records held by the Nova Scotia
Museum.

Strophitus undulatus is a long-term brooder, eggs being fertilized in summer and released the next spring. The reported host fish are Golden shiner, Common shiner, Creek chub and Yellow perch (See Table. 2).

Status rank has been determined by COSEWIC as 4 “secure” nationally and 2 “maybe at risk” in Nova Scotia. The status of New Brunswick populations has not been determined. There is some evidence for a decline in the number of occurrences in Nova Scotia since 1960. This is a “species of concern” in the State of Maine. (Nova Scotia General Status “Red”)

***Pyganodon cataracta* (Say, 1817)**

(= *Anodonta cataracta* Say, 1817)

Eastern floater

Plate II: 14, 15 and 16; Figure 10: Summary of Records in Nova Scotia

Pyganodon cataracta is one of the most common and widespread of freshwater mussels in Nova Scotia. It was first reported for the Province by J.R. Willis (1863) as “*Anodonta fernssaciana*” (sic). Clarke and Meachem Rick (1963) consider Willis’ Nova Scotia specimens, examined at the British Museum (Natural History), to be intergrades between *A. cataracta cataracta* and *A. cataracta fragilis*. The first specimens acquired by the NSM were collected in the 1940’s and 1950’s, particularly by D. Livingstone and H.D. Athearn, with additional specimens collected by G.H. Cox who collected specimens at Grant Lake, Pictou County in 1946. Many specimens were collected and records made by Museum staff and others during the 1960’s through 1990’s with substantially more by the NSDNR survey 1999 to 2004. At present the NSM has 242 specimen lots from Nova Scotia and another 12 from other areas including 9 lots from New Brunswick.

Pyganodon cataracta is quite variable in its form in Nova Scotia as has been described by Athearn and Clarke (1962), Clarke and Meachem Rick (1963), Clarke (1981) and Kat and Davis (1984). As a result species and subspecies names have been applied, based on shell characteristics, particularly the bar sculpture at the umbones described as “single” looped for the Newfoundland floater, *P. fragilis* and “double” looped for the Eastern floater, *P. cataracta* (Nedeau *et al.*, 2000). In this study all have been referred to as *P. cataracta*.

The shell valves are elongate and up to 150mm in length, but generally about 100mm. They are thin and fragile, inflated along the sides with low umbones that show characteristic looped umbone sculpture, as previously mentioned. The umbones are often eroded, obscuring this characteristic. There are no hinged teeth. The periostracum is smooth, glossy and variably yellowish, greenish or brownish-black in colour. Two prominent green rays are often present on the posterior slope. Growth rings are prominent. The interior nacre is blue-silver in colour, thin and without regions of thickening.

The range is the Atlantic coastal drainage from the Gulf of Mexico, north to the Great Lakes and Lower St. Lawrence River. It occurs generally in New Brunswick, Prince Edward Island and Nova Scotia. The populations in Cape Breton Island as well as Anticosti Island and Newfoundland are thought by Clarke (1981) to be *P. fragilis*. *Pyganodon cataracta* occurs commonly throughout Nova Scotia.

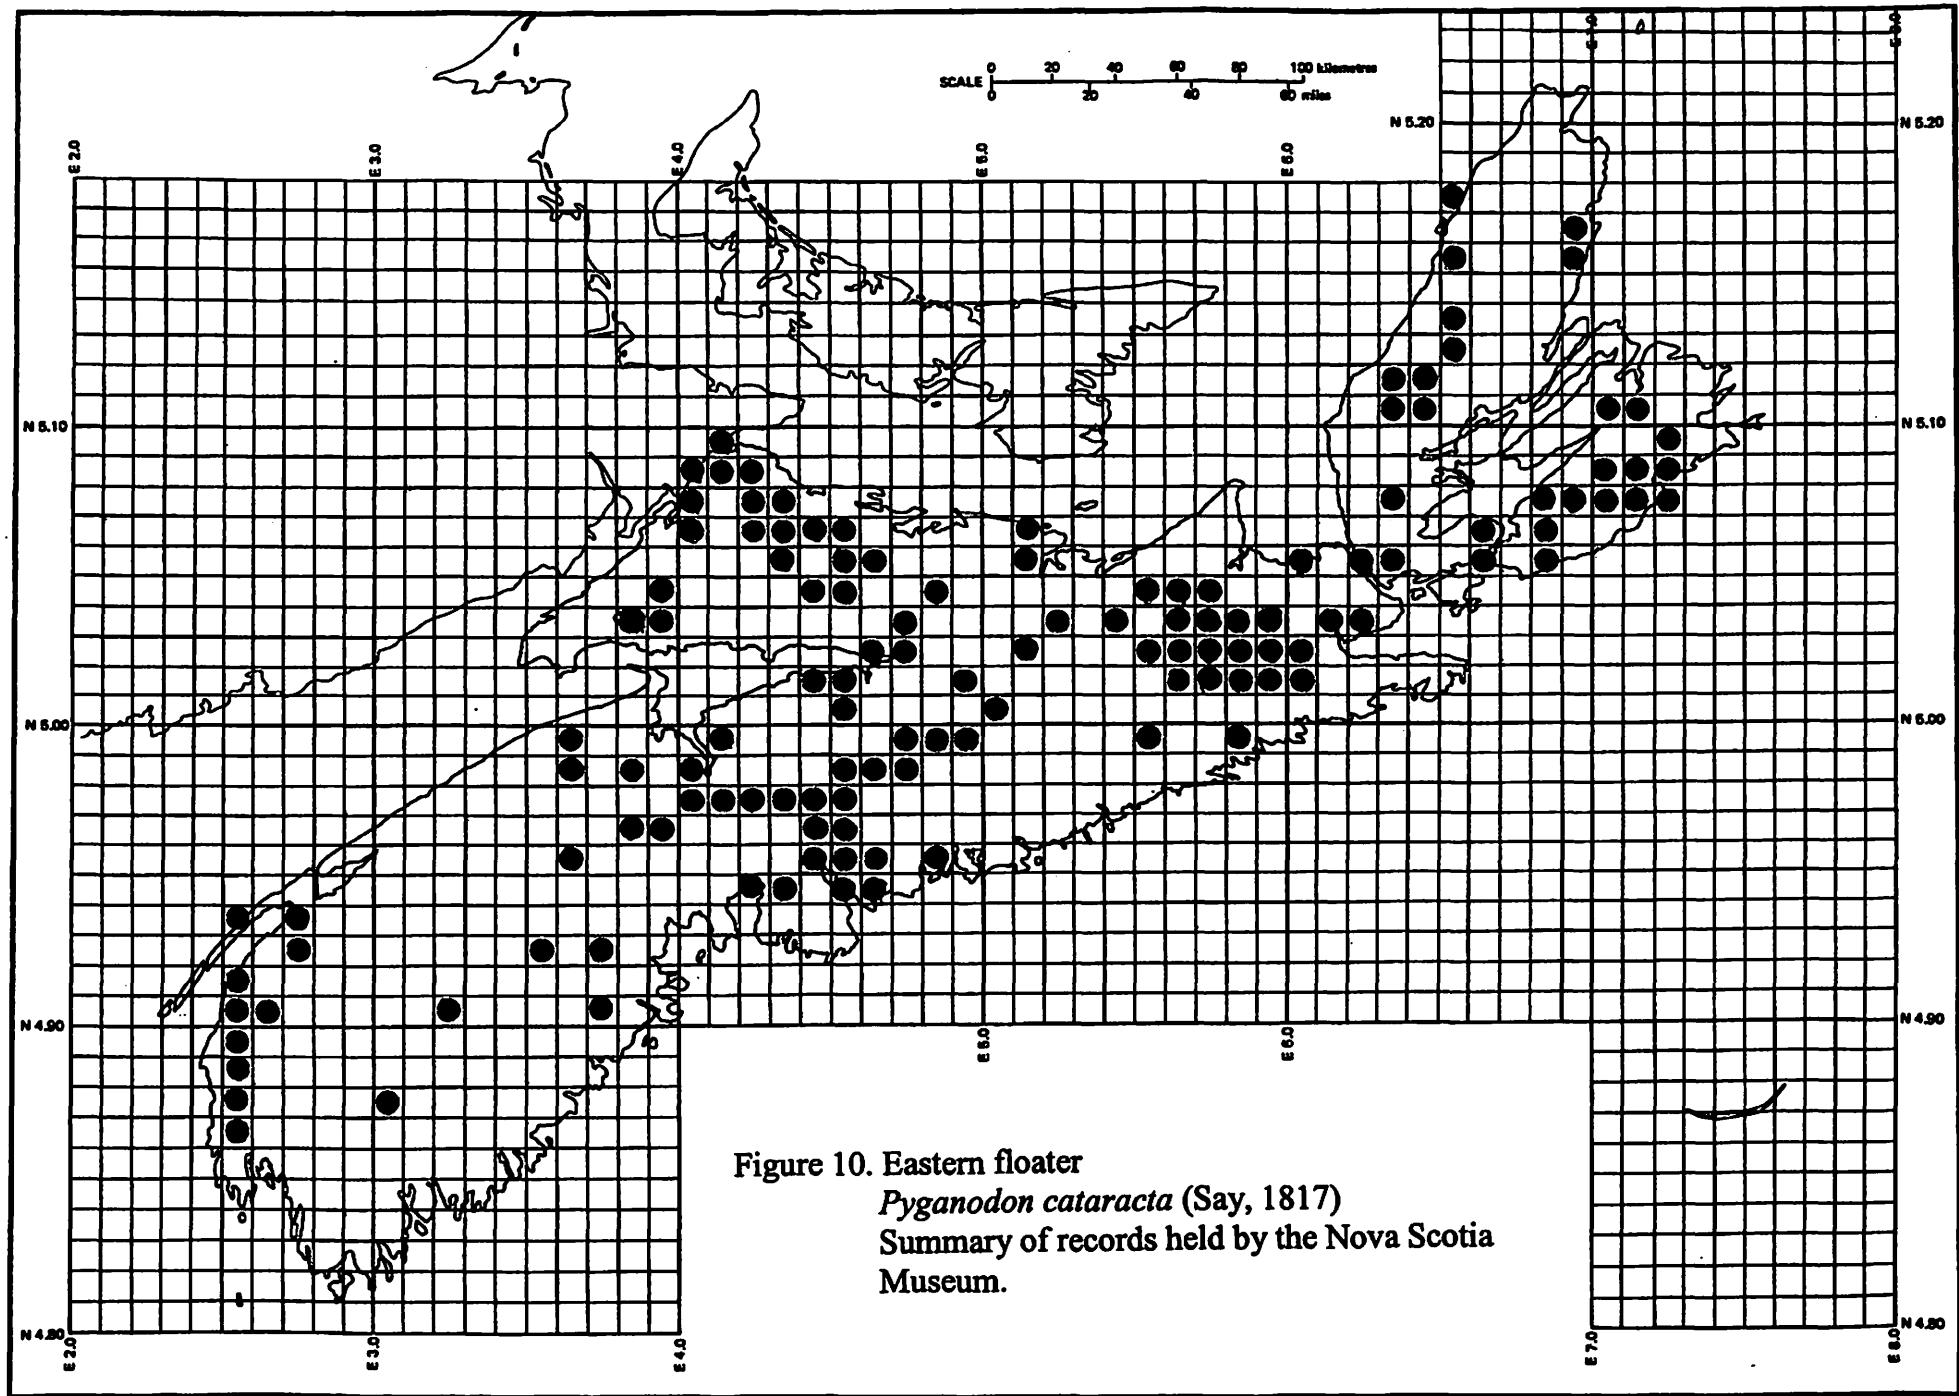

Figure 10. Eastern floater
Pyganodon cataracta (Say, 1817)
Summary of records held by the Nova Scotia
Museum.

A wide range of habitats is occupied including slow-running streams of various sizes, lakes and ponds including river ox-bow ponds and gravel pits. One unusual habitat is sink-hole ponds in gypsum karst areas, where the animals are often isolated from other populations and grow to large sizes, c. 150 mm lengths, with thick shells. Pre-Wisconsinan sub-fossil specimens (c. 84,000 BP, Godfrey-Smith *et al.* (2003)) have been found in ancient sink hole ponds in a gypsum quarry at East Milford, N.S. (NSM collection). A wide range of substrates is used from gravel to soft mud. It is found in all water except those with pH below 5.0. Host fish are White sucker and Three-spined stickleback (See Table. 2).

Pyganodon cataracta has been rated by COSEWIC (2006) to be nationally level 4 “secure” and similarly “secure” in Nova Scotia, New Brunswick and Prince Edward Island. (Nova Scotia General Status “Green”)

***Anodonta implicata* Say, 1829**

Alewife Floater

Plate II: 17 and 18; Figure 11: Summary of Records in Nova Scotia

The earliest record of *Anodonta implicata* in the NSM collection is from the Shubenacadie River, made by H. D. Athearn in 1948, but the species has been known in Nova Scotia since 1863 (Willis, 1863). The collections made by Athearn and Clarke (1962) and Clarke and Meachem Rick (1963) laid the foundation of the current material and knowledge of this species in the province. Museum collecting up to 1999 and the 1999-2003 DNR Survey have provided the most recent material with 93 specimen lots available. There are also three lots from New Brunswick and one from Massachusetts.

The form and colour of Nova Scotia specimens are generally as described in the literature with fully grown individuals up to 140 mm. in length and yellowish-brown to black in colour. In the past some large (c. 145 mm. length) *Anodonta* mussels from small ponds, including sink hole ponds in gypsum, have been identified as *A. implicata*. The shells of these specimens are very glossy, show internal thickening which is not restricted to the anterior end and the colour is yellow brown. These confusing specimens are considered to be *Pyganodon cataracta*.

The species ranges from South Carolina north to Maritime Canada: Southern New Brunswick and Nova Scotia but not Prince Edward Island. Clarke and Meachem Rick (1963) describe the distribution as sporadic and this holds true from the present study where many known occurrences have been confirmed and new populations identified. Distribution is in coastal areas with larger streams which have runs of the host fish species; Gaspereau (Alewife), Blueback herring and American shad (See Table. 2). Major populations are in Musquodoboit River, St. Mary’s River, River Inhabitants, Mira River, Margaree River, Wallace River, Parrsboro River, Shubenacadie River, Avon River, Black River, Gaspereau River, Annis River, LaHave River and Shubenacadie Canal and Dartmouth Lakes. Some apparent gaps in the distribution may be due to acidic waters ($\text{pH} < 5.0$) and/or lack of survey effort (Southwest Nova Scotia). It mostly occurs on sand and gravel bottoms in lakes, ponds and rivers, including tidal freshwaters.

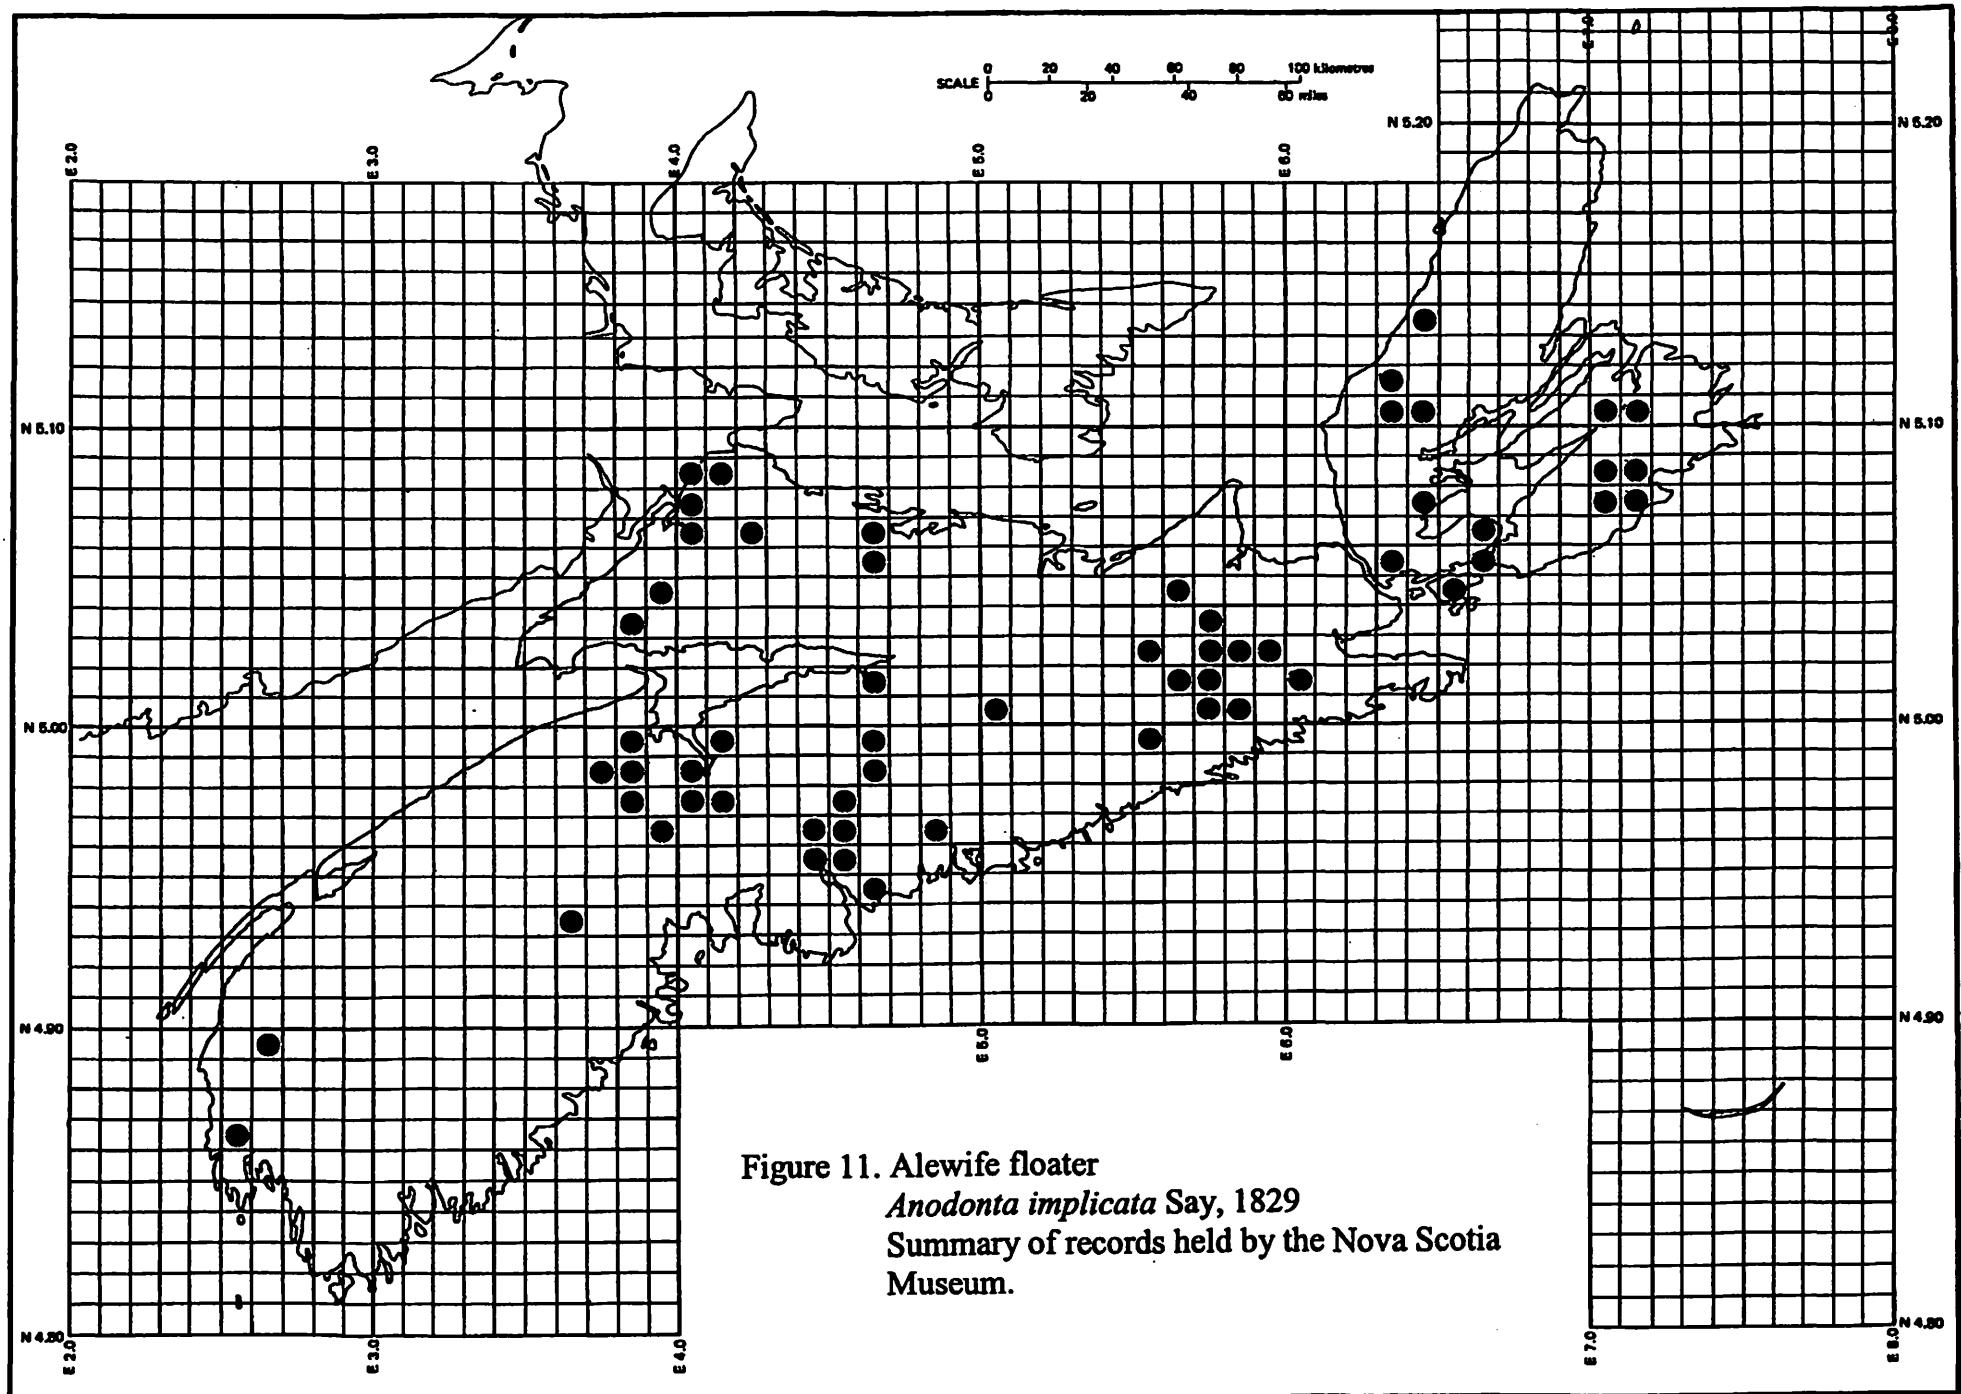

Figure 11. Alewife floater
Anodonta implicata Say, 1829
Summary of records held by the Nova Scotia
Museum.

Anodonta implicata is currently ranked by COSEWIC (2006) both provincially and nationally at Level 4, "Secure". (Nova Scotia General Status "Green")

***Lampsilis cariosa* (Say, 1817)**

Yellow lampmussel

Plate III: 19, 20, 21 and 22; Figure 12: Summary of Records in Nova Scotia

Prior to 1962 there were no published records of the Yellow lampmussel in Nova Scotia and due to problems in taxonomy the status of this species in Canada was in doubt (Clarke and Meachem Rick, 1963). The discovery of a population in Sydney River was therefore of some significance. For the following 40 years studies have documented the continued survival of the species in the Sydney River, but, despite extensive survey efforts, no other populations have been discovered in Nova Scotia. A status report on *Lampsilis cariosa* was prepared for COSEWIC and a draft submitted in 2001 (Davis *et al.* 2003). It was considered as being a Species of Special Concern in 2003. More recently the presence of *L. cariosa* in the Saint John River, New Brunswick has been confirmed and the species appears to be quite common in the lower reaches of the river. The NSM has 9 specimen lots from Sydney River in its collection.

Lampsilis cariosa is well described and illustrated by Clarke (1981), Nedeau *et al.* (2000) and Strayer and Jirka (1997). It is a large (up to 100mm length) ovate species. The surface is smooth with growth rests and the periostracum smooth, polished, orange-yellow to yellow-brown in colour. Some individuals have fine green lines in the periostracum on the posterior dorsal slope of the shell. Internally the nacre is white or bluish-white sometimes with pink or orange in the umbone cavities. The hinge teeth are complete and well-developed. There is sexual dimorphism in this species. The shells of females have greater depth at the posterior end.

The general distribution of this species is the Atlantic drainage from Cape Breton Island south to the Ogeechee River in Georgia. The northern populations are disjunct from the main populations by hundreds of kilometers. It is widely distributed but somewhat rare in Maine, being listed as 'threatened' in that state. The Canadian populations are in southern New Brunswick and Cape Breton Island, Nova Scotia. The NSM has records from Sydney River, Blacketts Lake and Gillis Lake. All sites are in *Natural History of Nova Scotia* Units 531 and 585.

The typical habitat is larger streams but it is also found in lakes. The substrate is mainly sand on exposed shores or in swift currents. In Sydney River the waters tend to be alkaline with pH 7.2 to 7.5 (Alexander *et al.*, 1986). *L. cariosa* is a long-term brooder, eggs are fertilized in late summer and the glochidia released the following spring. The host fish in Nova Scotia are White perch and Yellow perch (See Table. 2).

Status rank has been determined by COSEWIC nationally as 3 "sensitive", for New Brunswick as 3 "sensitive" and for Nova Scotia 2 "maybe at risk. (Nova Scotia General Status "Red")

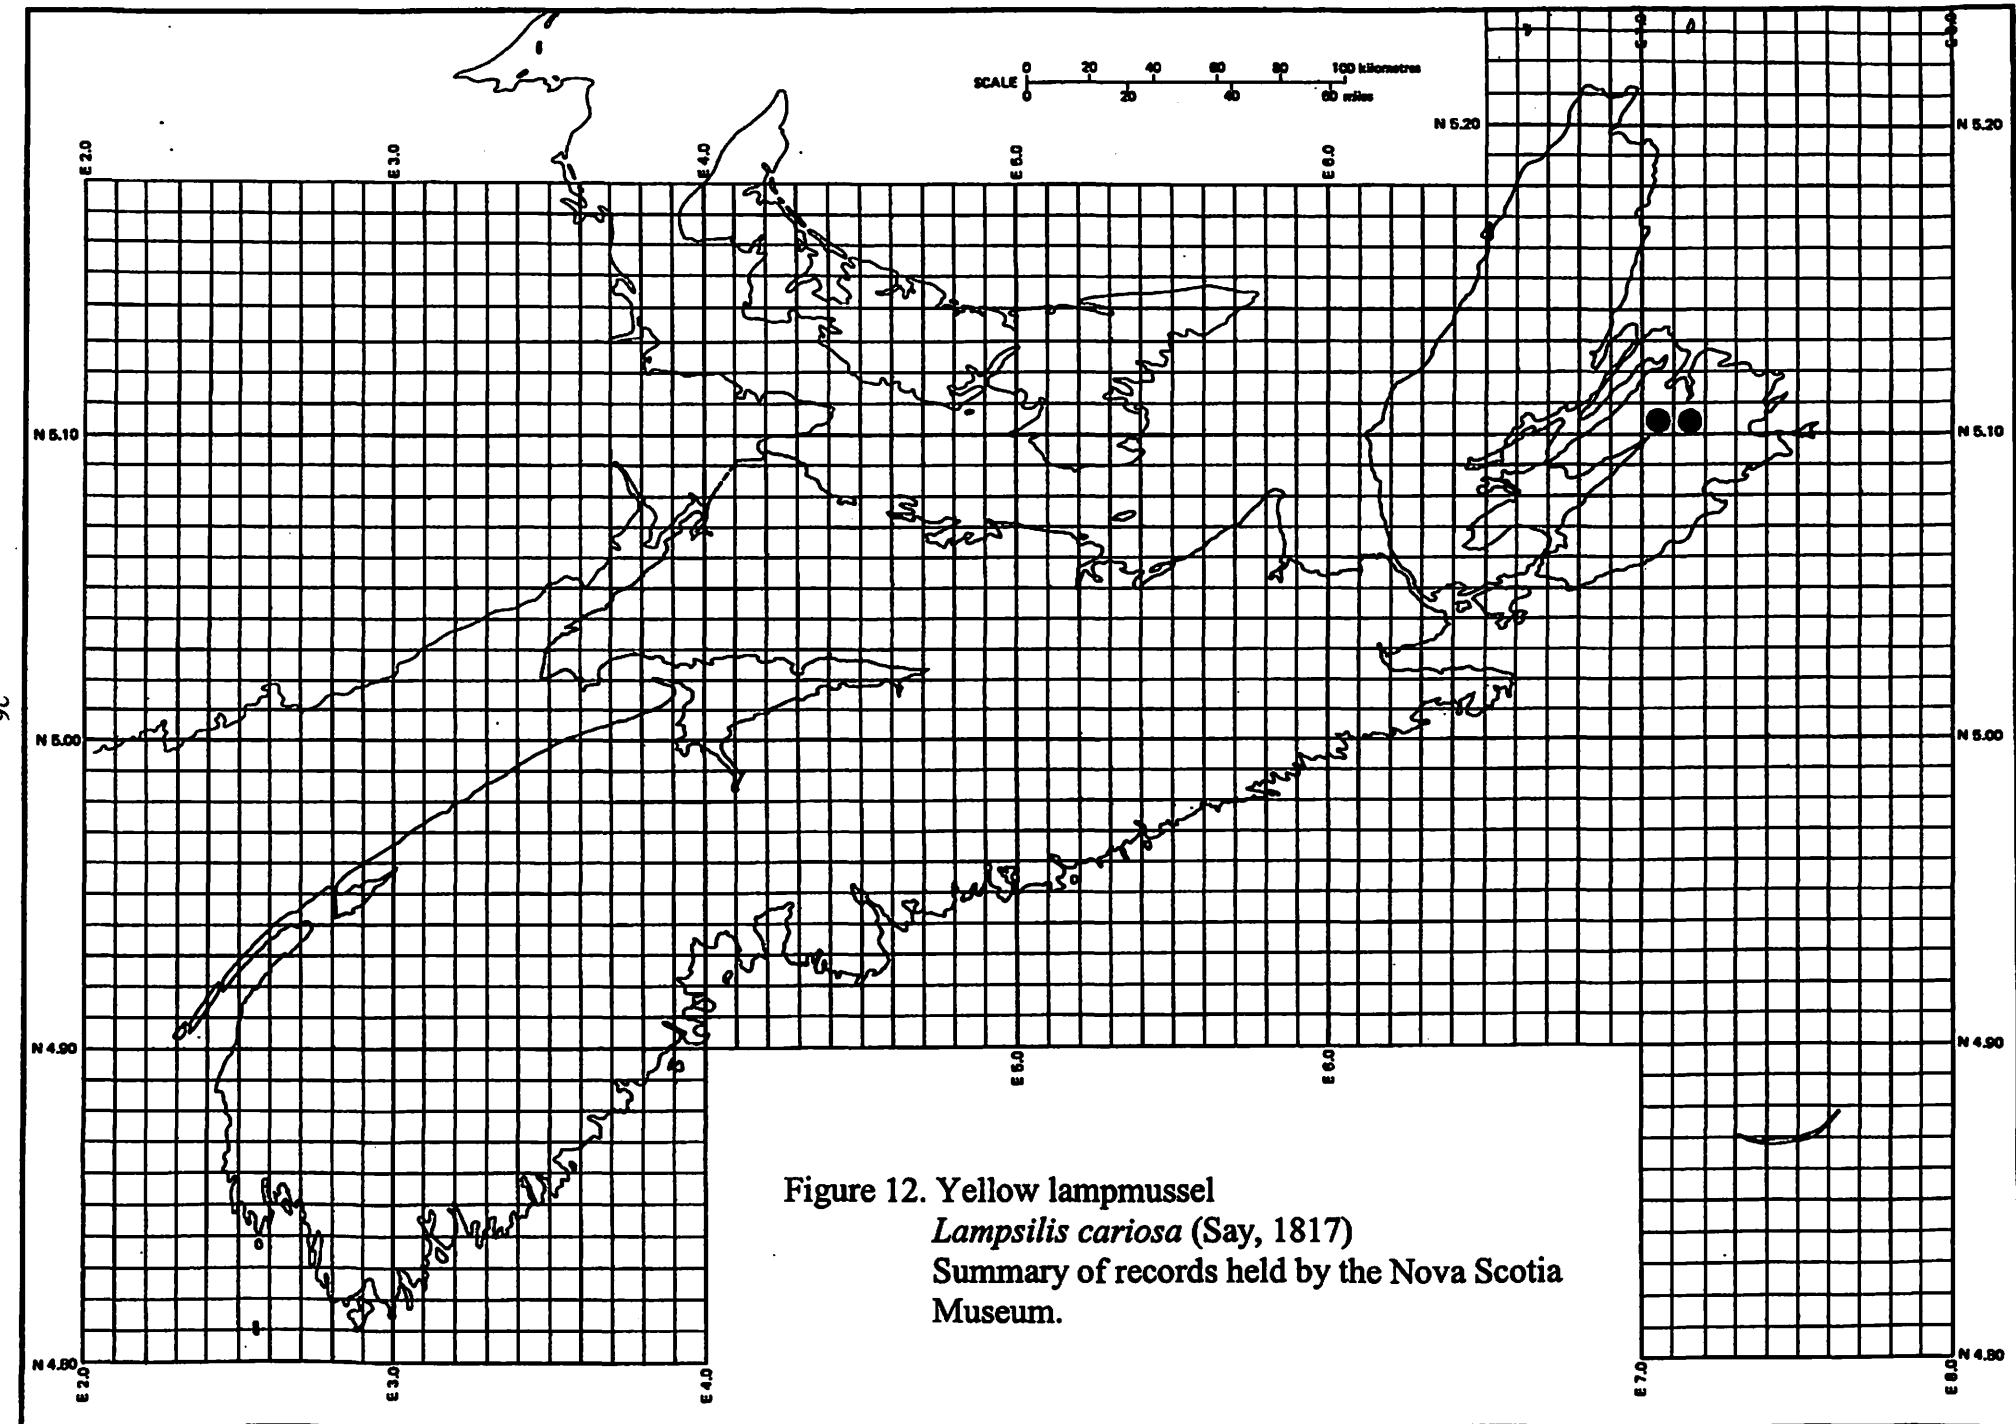

Figure 12. Yellow lampmussel
Lampsilis cariosa (Say, 1817)
Summary of records held by the Nova Scotia
Museum.

Lampsilis radiata (Gmelin, 1791)

Eastern lampmussel

Plate III: 23 and 24; Figure 13: Summary of Records in Nova Scotia

In the literature this species is often referred to as *Lampsilis radiata radiata*, including the subspecific name to distinguish typical *radiata* from other subspecies that do not occur in Eastern Canada (Clarke, 1981). Willis (1863) first reported this species in Nova Scotia as “*Unio radiata*, Lam. Grand Lake, on line of Nova Scotia Railroad; not common.” The first specimens obtained by the NSM were collected by Dr. G.H. Cox, an amateur malacologist, about 1950, from localities in Pictou County. Some other specimens resulted from the work of H.D. Athearn particularly in 1953 and 1954 (Athearn and Clarke, 1962). From 1975 onwards D.S. Davis and colleagues at the Museum collected specimens from eleven localities but the significant effort, in 1999–2003, came from the survey work of NSDNR which added many new localities and specimens to the collection. Currently the Museum has 60 specimen lots from Nova Scotia, 5 from New Brunswick, 1 from Quebec, 2 from Ontario and 2 from New York State.

Lampsilis radiata is a fairly distinct species, up to 100mm in length with an elliptical outline in males but expanded in the posterior ventral margin in females. This strong sexual dimorphism is also seen in *L. cariosa* and *Leptodea ochracea*. The periostracum is yellowish-brown to dark brown, with numerous dark rays. The interior nacre is white to bluish-white or pink. The hinge teeth are well developed with 3 pseudocardinal teeth in the right valve and 2 in the left. Lateral teeth are straight or slightly curved; one in the right valve and 2 in the left. In Nova Scotia there is the chance of confusing this species with the rayed form of *Elliptio complanata* and specimens should be examined carefully.

This species has a broad geographic range from the lower Great Lakes and Atlantic Canada south to South Carolina. In Canada it occurs in Ontario, Quebec, New Brunswick and Nova Scotia. It has not been reported from Prince Edward Island or Newfoundland and Labrador. Figure 12 shows a summary of the records for Nova Scotia. In northern and central Nova Scotia the main population centre appears to be Cumberland, Pictou and Antigonish counties and the St. Mary’s River, Stewiacke River, Musquodoboit River, Shubenacadie River and in the Shubenacadie Canal system.

It has not been recorded in Cape Breton Island and is apparently absent from southwestern parts of the Province, although this area has not been fully surveyed. It is present in *Natural History of Nova Scotia* Regions 500 and 600 and in Units of Regions 300 and 400 where glacial till is sufficient to buffer acidic waters.

The habitat is both lakes and rivers with bottoms of gravel or sand and rarely mud. Strayer (1993) has characterized the habitat as larger streams.

Lampsilis radiata is a long-term brooder where fertilized eggs are retained by the female from August through to August of the following year when the glochidia are released and become parasitic in White perch or Smallmouth bass (See Table. 2). With the incremental expansion of the introduced Smallmouth bass, through illicit stockings, their range may expand (Hebda *et al.*, 1990).

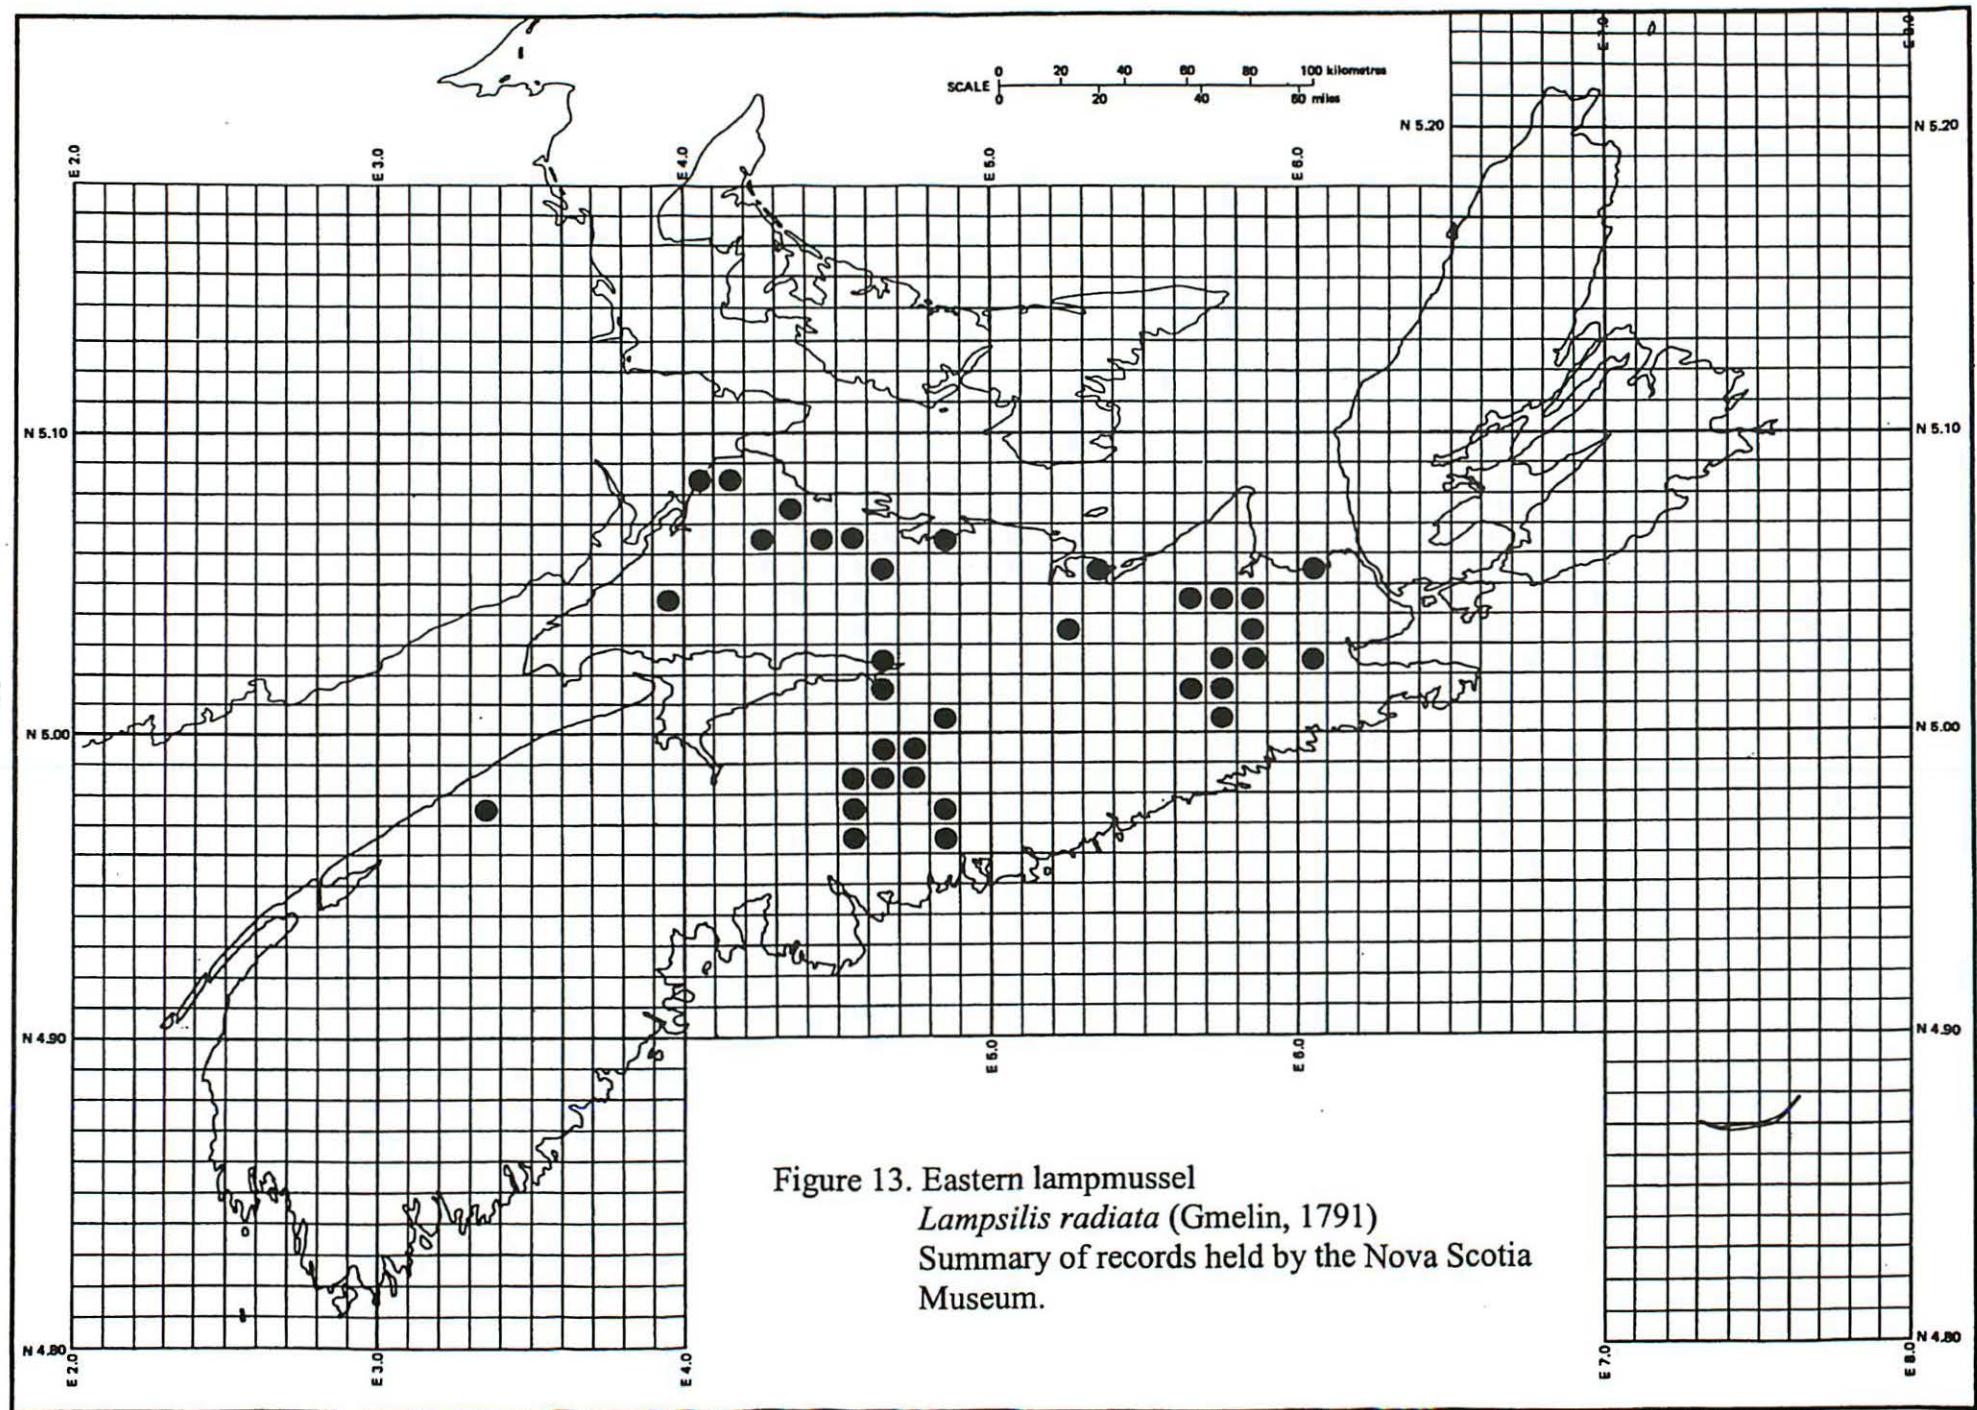

Figure 13. Eastern lampmussel
Lampsilis radiata (Gmelin, 1791)
Summary of records held by the Nova Scotia
Museum.

Status rank has been determined by COSEWIC as 4 “secure” nationally and in New Brunswick and 3 “sensitive” in Nova Scotia . (Nova Scotia General Status “Yellow”)

***Leptodea ochracea* (Say, 1817)**
(=*Lampsilis ochracea* (Say, 1817))
Plate III: 27 and 28; Figure 14.

Tidewater mucket

H. D. Athearn was the first to report this species in Nova Scotia, in about 1954, from River Hebert, Cumberland County (Athearn and Clarke, 1962). Not long after A. Meachem Rick made additional records in Cumberland County and in Sydney River, Cape Breton County (Clarke and Meachem Rick, 1963). NSM staff found a new population in Placides Lake, Digby County (Wright, B 1979) and revisited Newville Lake, Cumberland County in July 1989. The NSDNR survey, begun in 1999, also discovered some additional sites in Cumberland County (Long Lake and Round Lake), and also revisited River Hebert and Newville Lake. The NSM has 13 specimen lots from Nova Scotia, 2 lots from New Brunswick and 1 lot for North Carolina.

The Tidewater mucket is a medium-sized mussel with shell up to 75mm long and 50mm high and ovate in form. Males are a little more elongated and bluntly-pointed posteriorly while the females are more rounded posteriorly. Growth rests are easily seen and there are concentric dark lines or wrinkles between growth lines. The colour of the periostracum is yellowish- or greenish-brown and specimens may be with or without fine green radiating lines which are not restricted to the posterior dorsal slope. The nacre is pink or salmon coloured. Weak pseudocardinal teeth are present just anterior to the umbones. The lateral teeth are weakly developed. For good descriptions and illustrations of *Leptodea ochracea* see Clarke (1981) and Nedeau *et al.* (2000).

The general distribution of *L. ochracea* is the Atlantic Coastal Plain from the Savannah River, Georgia north to southern New Brunswick and Nova Scotia, which are the only populations in Canada. In Nova Scotia all known localities are close to the coast with records from Sydney River, Cape Breton County, Tantramar Marshes (Round Lake and Long Lake), Newville Lake and River Hebert in Cumberland County and Placides Lake, Digby County. *Natural History of Nova Scotia* Units 411, 532, 581 and 585 and District 560.

Strayer (1993) has suggested that the main habitat preferred by *L. ochracea* is tidal waters, but in Nova Scotia most habitats are small lakes and some streams. All streams drain to either the Atlantic Ocean directly or via the Bay of Fundy and sites are no more than 15km from the coast. The associated bottom types are sand or mud. The pH, where recorded, is generally high (alkaline) 6.5 to 7.5 (Alexander *et al.*, 1985).

Leptodea ochracea is a long-term brooder where eggs are fertilized in late summer and released the following spring. The host fish in Nova Scotia is Gaspereau (Alewife).

The status rank has been determined by COSEWIC as 4 “secure” nationally and in New Brunswick, but 3 “sensitive” in Nova Scotia. (Nova Scotia General Status “Yellow”)

Museum.

Recommendations for Future Work (not in order of priority)

1. Survey for freshwater mussels should be continued to complete the coverage of Nova Scotia, in particular southwestern areas; Annapolis, Digby, Yarmouth, Shelburne and Lunenburg counties, the interior of Halifax County, southern Cumberland and Colchester counties and Cape Breton Highlands. The methods used by NSDNR in the 1999-2003 study should be employed to obtain comparative data.
2. University-based research should be encouraged to add to our knowledge of breeding and host/parasite relationships, ecology and genetics of local mussel species.
3. Several sites with good species diversity and historic data should be established as monitoring sites. Provincial parks can provide some level of protection at these sites, e.g. Newville Lake (Halfway River Provincial Park), Cumberland County, Lochaber Lake (Lochaber Lake Provincial Park), Guysborough County.
4. Analyses of NSDNR results to look at ecological aspects e.g. *Elliptio complanata* radiate forms.
5. Initial steps should be taken to understand the diversity, distribution and ecology of the Sphaeriidae in Nova Scotia.
6. During the course of regular fieldwork maintain a watch for invasive Zebra and Quagga mussels which are currently a major threat to native freshwater mussels in Canada.
7. Consideration should be given to preparation of a popular field guide to freshwater mussels in Atlantic Canada.

MUSSEL SURVEY DATA FORM

OBSERVER: Jenny Costel, Butch Galvez DATE: June 24 2004
 WATER TYPE: Lake L = Lake, Pond W = All others SITE NUMBER: #1
 WATER NAME: Second Lake WATERSHED: Shubenacadie
 TOWN: Hr. Sackville COUNTY: Halifax
 SURVEY TYPE: Shoreline (on foot) DURATION OF SURVEY: 30 minutes

DIRECTIONS: (landmarks, include sketch if necessary): MAP Bk 5th Edition of 58/45/C2

UTM GRID: 04472 74 EAST, 4959250 NORTH
 (NAD 83)

ECODISTRICT: _____

DESCRIPTION OF LOCAL HABITAT (Land Use, Depth/Flow/Substrate, etc)

- Lakeshore has a substrate of gravel, silt and sand (some muck)
- Horsetails abundant in spots
- Mussel shells fairly common in some areas (muskat middens)
- Live individuals not abundant, but in small isolated areas common

SPECIES FOUND AND RELATIVE ABUNDANCE: X = Live Individuals, S = Shells Only

Elliptio - TNTC A. undulata } occasional to rare
16745 A. implicata }

MM EC AU AV PC AI SU LO LC LR

16746 Elliptio most common species found at this location

Numerous shells found.

- A. undulata → only a few shells found
- A. implicata → only a few shells found

NOTES ON MORTALITY, REPRODUCTION, SHELL EROSION, ETC:

- Mussel shells common in some areas (particularly where
- Shells are in reasonable shape and not muskrat feed)
- Badly eroded
- Lake is used by locals for swimming, fishing and boating
- Survey location is not developed, but some houses are

ADDITIONAL COMMENTS:

built along north edge of lake

Appendix III

Unionacea specimen lots from outside Nova Scotia in MIMS database.

Included are all lots collected in New Brunswick, the island of Newfoundland, Ontario, Quebec, Northern United States of America and other parts of the world. Several smaller collections at the Nova Scotia Museum have not been curated, but will be incorporated in the future.
